APPENDIX D: FEDERAL AND STATE CONTACT SUMMARIES

THIS PAGE LEFT INTENTIONALLY BLANK

BRRTP FEDERAL CONTACT SUMMARIES

Agency	Study Component	Date	Type of Contact	Summary
US Forest Service, Angeles National Forest, Janet Nickerman	Species list	09 January 2008	Email	USFS provided Angeles National Forest sensitive species list.
Bureau of Land Management, Ridgecrest Field Office, Shelly Ellis	Species list	06 March 2008	Email	BLM provided their sensitive species list.
US Forest Service, Angeles National Forest, Arcadia Office	Sensitive Wildlife Species	25 March 2008	Meeting	Discussed sensitive wildlife species and habitat, survey needs, survey approach and potential impact of transmission line.
US Forest Service, Marian Kadota	Plant Management Plans	01 April 2008	Written Communication	USFS provided copies of the Forest Service plant management guides.
US Fish and Wildlife Service, Ventura Office	Species list	02 April 2008	Written Communication	Request for Special-Status Species List for the Barren Ridge Renewable Transmission Project, Kern and Los Angeles Counties.
US Forest Service, Angels National Forest, Nancy Sandburg and Janet Nickerman	Survey Approach	03 April 2008	Email	Requested review of survey approach for the BRRTP.
US Forest Service, Angeles National Forest, Arcadia Office	Sensitive Plant Species	04 April 2008	Meeting	Discussed sensitive plant and invasive species in study area, survey needs, survey approach and potential impact of transmission line.

BRRTP Federal Contact Summaries (continued)

Agency	Study Component	Date	Type of Contact	Summary
US Fish and Wildlife Service, Ventura Office	Species list	01 May 2008	Written Communication	USFWS provided list of species fulfilling the requirements of the USFWS under Section 7(c) of the Endangered Species Act.
US Fish and Wildlife Service, Ventura Office, Chris Dellith	Protocol Surveys for Amphibian species	08 May 2008	Telephone	USFWS reviewed the amphibian site assessment report and gave verbal approval to proceed with protocol surveys.
US Forest Service, Angeles National Forest, Katie VinZant	Botany Surveys	08 May 2008	Meeting	Discussed the Botany Surveys, Seed Collection and use of Herbicides.
US Forest Service, Angeles National Forest, Ann M Berkley	GIS data	09 May 2008	Email	Spotted Owl shapefiles provided for the Project Area.
US Forest Service, Angeles National Forest, Ann M Berkley	GIS data	12 May 2008	Email	USFS provided Arroyo Toad and CA red-legged frog GIS habitat data.
US Forest Service, Angeles National Forest, Justin Seastrand	Avian Risk Assessment	12 May 2008	Email	USFS provided a draft avian risk assessment report.
US Fish and Wildlife Service, Ventura Office, Ashleigh Blackford	Desert Tortoise	20 May 2008	Telephone	Discussed habitat assessment for desert tortoise and USFWS recommended survey approach.

BRRTP Federal Contact Summaries (continued)

Agency	Study Component	Date	Type of Contact	Summary
US Forest Service, Angeles National Forest, Nancy Sandburg	Fauna and Flora Records	06 June 2008	Email	USFS provided Flora and Fauna spreadsheet for recording data.
US Fish and Wildlife Service, Ventura Office, Della Snyder-Velto	Wildlife Species	12 June 2008	Telephone	Discussed survey needs and wildlife in study area.
US Fish and Wildlife Service, Ventura Office, Della Snyder Velto	Unarmored three-spine stickleback	12 June 2008	Email	Discussed analyzing effects of the action to UTS.
US Forest Service, Angeles National Forest, Katie VinZant	Botany reports	20 June 2008	Email	USFS provided template for the ANF requirements for botany reports.
US Fish and Wildlife Service, Arcadia Office. Della Snyder-Velto	Sensitive Species and ESA Section 7	17 July 2008	Meeting	Discussed Biological Surveys, ESA Section 7, Biological Assessment, and Consultations.
US Fish and Wildlife Service, Hopper Mountain NWR Complex, Chris Barr	CA Condor	21 July 2008	Email	USFWS provided zip file containing GIS shapefile of all Global Positioning System (GPS) records since 2005 within the Project area.
US Forest Service, Angeles National Forest, Patricia Krueger	RCA's	31 July 2008	Email	USFS provided Forest Service Handbook on Soil and Water Conservation

BRRTP Federal Contact Summaries (continued)

Agency	Study Component	Date	Type of Contact	Summary
Bureau of Land Management, Ridgecrest Field Office, Linn Gum	Mojave ground squirrel	01 August 2008	Email	Discussed the MGS and review of the West Mojave Plan conclusively shows the area of interest for the BRRTP is not contained within the lands designated by MGS conservation area.
US Forest Service, Marian Kadota	CA Condor	01 August 2008	Email	Discussed the Federally listed CA Condor and impact of power line.
US Forest Service, Angeles National Forest, Patti Krueger	Avian Risk Assessment Report	04 September 2008	Email	A request had been submitted to USFS by Power for the missing figures and maps of the Avian Risk Assessment Report USFS provided as an example. Patti indicated that the missing information would not be available until mid-December.
US Forest Service, Angeles National Forest, Nathan Sill	RCAs	05 September 2008	Email	USFS provided additional data regarding the RCAs. This included GIS files, reports and clarification to questions regarding the 5-step process in identifying RCAs for BRRTP
US Fish and Wildlife Service, Della Snyder-Velto	Avian Risk Assessment	12 September 2008	Email	USFWS provided resource contact information to help with locating data and assessing risk for avian species.
USDA Forest Service, Angeles National Forest, Nathan Sill	RCA's and Biological surveys	22 October 2008	Meeting	Update on the progress of the biological surveys and reports. Also discussed RCA's.

BRRTP Federal Contact Summaries (continued)

Agency	Study Component	Date	Type of Contact	Summary
USDA Forest Service, Angeles National Forest, USFWS, and BLM	RCA's, biological surveys, and USFWS consultations	November 25 2008	Meeting	Discussed results of biological surveys and approach to Section 7 consultations.
USDA Forest Service, ANF and USFWS	BIO Tech Report, BA and schedule	October 29, 2009	Meeting	Discussed Bio tech report comments and BA schedule, including data needs.
USDA Forest Service, ANF	RCA's	December 9 2009	Meeting	Discussed Riparian Conservation Area Surveys
USDA Forest Service, ANF	RCA's	January 6, 2010	Field visit	Field visit with ANF Biologist Nathan Sill to review/refine RCA buffers along Segment G.
ANF, BLM, USFWS	Biological surveys, USFWS consultations	March 18, 2010	Meeting	Discussed results of 2009 biological surveys and Biological Assessment
ANF, BLM, USFWS	Biological Assessment, Avian Protection Plan, Section 7 Consultation Schedule	August 24, 2010	Meeting	Discussed Biological Assessment and data needs. Also discussed the Avian Protection Plan.

STATE CONTACT SUMMARIES

Agency	Study Component	Date	Type of Contact	Summary
CA Department of Fish and Game, Dan Blankenship	Sensitive Species	01 April 2008	Telephone	Contacted CDFG to establish the contact for the Project.
CA Department of Fish and Game, Dan Blankenship	Sensitive Species	16 April 2008	Meeting	Discussed the Project, survey needs and wildlife in study area.
CA Department of Fish and Game, Dan Blankenship	Sensitive Species	05 May 2008	Telephone	Discussed species range, potential sensitive species occurrences and potential to be found within the study area.
CA Department of Fish and Game, Dan Blankenship	Coast horned lizard	05 May 2008	Email	Requested information regarding the CHL and distribution data.
CA Department of Fish and Game, Edmund Pert	Response to NOP	09 May 2008	Written Communication	Provided comments and review of the biological resources within the proposed project and recommended information to be included in the DEIR.
CA Department of Fish and Game, Dan Blankenship	Mojave ground squirrel	13 May 2008	Email	Requested additional information on the MGS and the potential for it to occur in the study area. CDFG has indicated there is a potential for the species to occur in the study area.

State Contact Summaries (continued)

Agency	Study Component	Date	Type of Contact	Summary
CA Department of Fish and Game, Dan Blankenship	Desert sensitive species	22 May 2008	Email	Provided CDFG with the BRRTP contact with USFWS.
CA Department of Fish and Game, Annette Tenneboe and Dan Blankenship	Survey Approach	30 May 2008	Teleconference	Discussed sensitive species, survey needs, survey approach and established that Dan Blankenship will be the lead contact for BRRTP.
CA Department of Fish and Game, Annette Tenneboe and Dan Blankenship	Survey Update	28 July 2008	Email	Provided an update with the progress of the survey work.
CA Department of Fish and Game, Julie Vance	Desert Species	29 July 2008	Email	Annette Tenneboe notified POWER that she was no longer the CDFG Region 4 contact for BRRTP. Julie Vance was contacted to provide a new contact for Region 4.

Ms. Diane K. Noda,
Ventura Fish and Wildlife Office
U.S. Fish and Wildlife Service
Ventura, CA 93001

SUBJECT: Request for Special-Status Species List for the Barren Ridge Renewable Transmission Project, Kern and Los Angeles County

Dear Ms. Diane K. Noda:

The City of Los Angeles Department of Water and Power (LADWP), is proposing the Barren Ridge Renewable Transmission Project to access clean, renewable resources in the Tehachapi Mountain and Mojave Desert areas, and improve reliability and upgrade transmission capacity. The Forest Service, BLM, and LADWP will prepare a joint Environmental Impact Statement/Environmental Impact Report (EIS/EIR) for the Barren Ridge Renewable Transmission Project. The Forest Service, BLM, and LADWP have identified preliminary alternatives to the proposed project

The Barren Ridge Renewable Transmission Project spans a distance of approximately 75 miles from the Mojave Desert south to the San Fernando Valley. The project is located within northwestern Los Angeles County and southwestern Kern County. The project study area is generally defined by the following limits: the northern boundary is the southern slopes of the Tehachapi Mountains, eastern boundary parallels State Route 14, southern boundary generally parallels the Santa Clara River, and the western boundary parallels Interstate 5. The study area measures approximately 1,280 square miles. Within this study area several routing possibilities have been identified that traverse through the Antelope Valley, across Angeles National Forest, and public lands located in the Mojave Desert. Please refer to the enclosed map for the location of the alternatives currently being considered.

Power Engineers, Inc. is requesting a list of all species that are listed, proposed for listing, or candidates for listing as threatened or endangered under the Endangered Species Act that could occur within the Barren Ridge Renewable Transmission Line project area. The Notice of Preparation of a Draft Environmental Impact Report for the Barren Ridge Renewable Transmission Project will be sent to agencies on April 4, 2008.

There are several alternative corridors being proposed and a map of the proposed alternative corridors is attached. The project corridors are located in the following USGS 7.5-minute topographic quadrangle maps:

Agua Dulce
Black Mountain

Cache Peak
Del Sur

Fairmont Butte
Green Valley
Lake Hughes
La Liebre Ranch
Lebec
Liebre Mountain
Little Buttes
Mint Canyon
Mojave
Mojave NE
Monolith
Neenach School
Newhall
Ritter Ridge
San Fernando
Sleepy Valley
Soledad Mountain
Tylerhorse Canyon
Warm Springs Mountain
Whitaker Peak
Willow Springs

Please send or fax the requested lists to me at 714.507.2799. Thank you for your prompt attention. If you have any questions or need additional information, please call me at [redacted]

Sincerely,

Vanessa Gutierrez

To: **Roger Root, US Fish and Wildlife Service**

From: **Wendy Roberts, Garcia and Associates**

Date: **21 April 2008**

RE: **Site Assessments for California Red-legged Frog and Arroyo Toad in San Francisquito Canyon**

Attached please find 10 site assessment forms for amphibian surveys completed the week of 7-11 April 2008. These surveys were completed to evaluate habitat for California red-legged frog and the arroyo toad along a proposed alternative alignment for a transmission line from Barren Ridge to Castaic. This possible alignment generally parallels, and in a few places crossed, San Francisquito Creek, northeast of Santa Clarita in Los Angeles County, California. Attached to the forms are maps, photographs, and field notes. I have also attached my resume, and a map of the general area showing the location of the 10 site assessments. Since no site assessment forms exist in the protocol for arroyo toad, the site assessment form from the 2005 Protocol for the California red-legged frog was used.

We identified a probable California red-legged frog tadpole and called the Ventura office of US Fish and Wildlife Service to let them know of this finding. I spoke with Doug Cooper on 14 April 2008, and he identified you as the person most likely to handle surveys for the area around San Francisquito Canyon.

In the near future we would like to discuss with US Fish and Wildlife Service permission to begin conducting protocol-level surveys for the California red-legged frog and the arroyo toad. After viewing and evaluating the habitat along San Francisquito Creek we would like permission to conduct surveys for California red-legged frog at sites 1-5 and sites 9 and 10 (as numbered in the attached site assessment forms), and for the arroyo toad at sites 1-5 and sites 7 and 10.

Subject: Species List for the Proposed Barren Ridge Renewable Transmission Project, Kern and Los Angles County, California

Dear Ms. Gutierrez:

This letter is in response to your request of April 2, 2008, for information on endangered, threatened, proposed, and candidate species that could occur within the subject project area. The proposed work area and preliminary alternatives traverse the Antelope Valley and Angeles National Forest. Given that the Bureau of Land Management and Forest Service intend to prepare a draft environmental impact statement for the proposed action, we assume a Federal nexus for compliance with the Endangered Species Act of 1973, as amended, exists; therefore, our response is made pursuant to section 7(a)(2) of the Endangered Species Act of 1973, as amended (Act).

The enclosed list of species fulfills the requirements of the U.S. Fish and Wildlife Service (Service) under section 7(c) of the Endangered Species Act. The Forest Service and Bureau of Land Management as Federal co-lead agencies have the responsibility to review the proposed activities and determine whether any listed species may be affected. Because the agencies intend to prepare an environmental impact statement, the Forest Service and Bureau of Land Management have the responsibility to prepare a biological assessment to make a determination of the effects of the action on the listed species. If the Forest Service and Bureau of Land Management determine that a listed species is likely to be adversely affected, they should request, in writing through our office, formal consultation pursuant to section 7 of the Endangered Species Act. Informal consultation may be used to exchange information and resolve conflicts with respect to the listed species prior to a written request for formal consultation. During this review process, the Forest Service and Bureau of Land Management may engage in planning efforts but may not make any irreversible commitment of resources. Such a commitment could constitute a violation of section 7(d) of the Endangered Species Act.

Only listed species receive protection under the Endangered Species Act. We recommend that you review information in the California Department of Fish and Game's Natural Diversity Data Base regarding other sensitive species that may occur in the project area. You can contact the

California Department of Fish and Game at [redacted] for information on other sensitive species that may occur in this area.

If you have any questions regarding this matter, please contact Ashleigh Blackford of the Ventura Fish and Wildlife Office at [redacted].

Sincerely,

Raymond Bransfield

Slender-horned spineflower	*Dodecahema leptoceras*	E
Spreading navarretia	*Navarretia fossalis*	T

Key:
E - Endangered
T - Threatened
CH - Critical habitat
C - Candidate species for which the Fish and Wildlife Service has on file sufficient information on the biological vulnerability and threats to support proposals to list as endangered or threatened.

BARREN RIDGE RENEWABLE TRANSMISSION PROJECT

Phone Conversation: Chris (USFWS) and Vanessa Gutierrez (POWER)
Date: May 8, 2008

Chris was returning a call for Ashleigh Blackford who is the USFWS co-lead for this project. He indicated that they have reviewed the amphibian site assessment reports and are giving verbal approval to proceed with protocol surveys.

The ONLY area in which we should avoid is the San Francisquito Dam area. This site is currently being monitored.

He also indicated that Fish and Game located Unarmored Threespine Stickleback in Bouquet Creek. We need to look into this species and its potential to be impacted by the Project.

Della Snyder-Velto will be taking a co-lead position with this project. She is located in the Arcadia US Forest Service Office.

From: **Wendy Roberts, Garcia and Associates**

Date: **12 May 2008**

RE: **Site Assessments for California Red-legged Frog and Arroyo Toad in the Project Area for the Barren Ridge Renewable Transmission Project**

Attached please find another eight site assessment forms for amphibian surveys completed the week of 21 - 25 April 2008. These surveys were completed to evaluate habitat for California red-legged frog and the arroyo toad along proposed alternative alignments for a transmission line from Barren Ridge to Castaic. This project is now referred to as the Barren Ridge Renewable Transmission Project (BRRTP).

This memo follows the one dated 21 April 2008 that was forwarded to Roger Root of your office by Los Angeles Department of Water and Power (LADWP). I understand that you are now the lead biologists for amphibian surveys for BRRTP, and am thus sending this memo and site assessment forms to you. A second week of assessing sites was necessary to evaluate possible TES amphibian habitat for possible BRRTP alignments.

This second week of searching for amphibian habitat encompassed more areas near the line close to San Francisquito Canyon (running roughly over parts of Pettinger and Dry canyons at the southwestern end of the alignment), a site near Bouquet Canyon, and a site north of Castaic Lake; all in Los Angeles County, California. Attached to the site assessment forms are maps, photographs, and field notes. I have not attached my resume since I included it previously, but I have included a map of the general area showing the location of the eight site assessments. Since no site assessment forms exist in the protocol for arroyo toad, the site assessment form from the 2005 Protocol for the California red-legged frog was used. Site Assessments 12 and 13 appear to be about exactly one mile away from the CNDDB record for California red-legged frog in San Francisquito Canyon. I have attached the CNDDB record to this memo.

We would like to discuss with US Fish and Wildlife Service permission to begin conducting protocol-level surveys for the California red-legged frog and the arroyo toad. Also, we will be in the area of the BRRTP this week of May 12-17, 2008 starting some amphibian surveys. We are starting surveys as a good-faith effort to comply with requests from Angeles National Forest, which wants sufficient protocol-level surveys to characterize TES amphibian species presence in areas possibly affected by the project. Further, we want to comply with the arroyo toad protocol to conduct at least two surveys (one day and one night) during the month of May. Finally, we understand from advice by a biologist experienced with arroyo toad on the Angeles National Forest (Ruben Ramirez), that we are approaching the usual peak time to find this species breeding at some of the relatively high elevation arroyo toad sites on the Angeles NF.

After viewing and evaluating the habitat along at these sites during the week of 21 to 25 April 2008, we would like permission to conduct surveys for California red-legged frog at sites 11, 12, 13, 14, and 17 (as numbered in the attached site assessment forms), and for the arroyo toad at sites 12, 13, 14, and 18. I would like to discuss with USFWS sites 15 and 16, which take a long rugged hike to access, and are practical or safe to access at nighttime.

BARREN RIDGE RENEWABLE TRANSMISSION PROJECT

Phone Conversation: Ashleigh Blackford (USFWS) and Vanessa Gutierrez (POWER)
Date: May 20, 2008
Time: 10:00 AM
Purpose: Desert Tortoise Survey Needs

Vanessa received a call from Ashleigh Blackford of the Ventura Fish and Wildlife Office regarding BRRTP and desert tortoise and survey needs. USFWS has requested that we conduct a habitat assessment for the desert tortoise by walking in a zigzag pattern in areas that are suitable within our corridors. They are *not* requesting protocol surveys this year. USFWS anticipate we will conduct protocol level surveys when we have a footprint.

The habitat assessment using the zigzag pattern USFWS recommended will be conducted this summer. POWER also received permission to conduct these surveys outside the survey time period (March 25 – May 31) as indicated on the USFWS Desert Tortoise Guidelines.

BARREN RIDGE RENEWABLE TRANSMISSION PROJECT

Phone Conversation between: Della Snyder-Velto (USFWS) and Vanessa Gutierrez (POWER)
Date: June 12, 2008

Vanessa contacted Della regarding the consultation process for BRRT and survey needs/ protocols for federally listed species in the Angels National Forest. Della will be a co-lead with Ashleigh Blackford on the BRRTP and responsibilities are documented below:

- Della Snyder-Velto will be the contact for the federally listed species in the Angeles National Forest
- Ashleigh Blackford will be the contact for the federally listed species in the desert.

She mentioned that the unarmored threespine stickleback(UTS) is located in the San Francisquito Creek, whole length of the Bouquet Creek, and Soledad Creek. USGS will be conducting a three year survey along the San Francisquito Creek for the stickleback and CA red-legged frog. Forest Service has also contracted USGS to survey for the stickleback in Bouquet Creek and no start date has been developed for this yet.

USFWS recommended that BRRT survey for the species in Bouquet Creek and be cautious that they may be breeding with the armored species.

Della will provide reports regarding the stickleback.

Below is here contact information through August. Starting in September she will be in the Ventura Office permanently.

To: Vanessa Gutierrez 2729
Subject: Re: Barren Ridge Survey Question

Based on the known presence of the species and the reports I just sent you, you can assume presence of UTS in Bouquet Creek.

Regarding your approach to analyzing effects of the action, I think it is necessary to establish whether or not listed species habitat is present, the quality of habitat, and what direct and indirect impacts would to habitat may occur from project activities. If you assume presence of species and/or habitat, the Service will have to assume that all habitat is suitable and essential to the species and therefore, impacts would potentially be adverse. It may be that impacts would be localized instead of widespread; it's easier to address localized impacts to habitat and design effective measures to reduce the effects in those areas. We also need to quantify in some way impacts from sedimentation and erosion on aquatic systems. Detailed habitat assessments might help in this respect.

Subject
Barren Ridge Survey Question

Hi Della,

As I'm forecasting the survey work I've got one additional question regarding the unarmored three-spine stickleback (Gasterosteus aculeatus williamsoni). Since we have known locations for this species and they are restricted to these sites, do we need to re-survey the known locations or can we assume presence and mitigate as necessary?

We are surveying every drainage that crosses under the preliminary corridors. This was requested by Forest Service so we can anticipate indirect impacts from construction. During this survey we are conducting a habitat assessments and streambed analysis to understand stream flow.

Please let me know what your thoughts are on this.

Thanks again,

MEETING MINUTES

SUBJECT: BRRTP Biology Meeting

MEETING DATE: July 17, 2008 **LOCATION:** Arcadia Forest Service Office

PROJECT NAME: BRRTP **PROJECT #:** 113807

PREPARED BY: Vanessa Gutierrez

TO:	LADWP	FS	BLM	USFWS
	Mark Sedlacek	Marian Kadota	Linn Gum	Della Snyder-Velto
	Chuck Holloway	Justin Seastrand	Robert Parker	Ashleigh Blackford
	Nadia Dale	Nancy Sandburg		
		Katie Vinzant		
	POWER			
	Jim Jensen			
	Mike Strand			
	Karen Cadavona			
	Vanessa Gutierrez			

ATTENDEES:

Nadia Dale, Della Snyder-Velto, Nancy Sandburg

1. Introductions

Patty Krueger will be working as the Forest Service biologist co-lead contact for BRRTP for the next three months. She will be assisting Nathan Sill who is also the lead for BRRTP.

2. Project Overview & Biological Surveys

All alternatives are currently being surveyed. This consists of a combination of protocol and habitat assessments. A habitat assessment was conducted for the riparian bird species this year and protocol surveys will be conducted next spring based on the results of the habitat assessment.

A detailed habitat assessment will be conducted for the desert sensitive species. This will consist of walking the 500-foot corridor where right of way entry is permitted. We will not be accessing private property.

Katherine Darst is the Ventura Fish and Wildlife lead biologist for the desert tortoise.

The project will be utilizing existing access roads and corridors. Surveys on the roads and spur roads will need to wait until design is completed. Timing of surveys for each new road and spur road will be based on the survey window for each biological resource.

MEETING MINUTES

3. Biological Resources

Forest Service discussed the Riparian Conservation Areas (RCA) and BRRTP needs to take this into account. If the project can not avoid the RCAs then this will be in direct conflict with the Forest Service Management Plan. An amendment will be needed to the Forest Service Plan if BRRTP does go through an RCA.

LADWP is currently accessing roads and spur roads and will avoid the RCAs.

Part of the RCAs is to assess the in stream sedimentation and erosion. This needs to include delineating the crane locations and expansion of existing roads. RCA widths are based on the stream type and resources that supported within each RCA.

4. ESA Section 7

The Biological Assessment will be submitted with the Draft EIS. BRRTP will also be going through Formal Consultations. USFWS agreed with this approach.

USFWS understands that multiple agencies are involved but one agency needs to take the lead. The lead agency will be responsible for terms and conditions for complying with the Biological Opinion.

USFWS is concerned with the endangered species on non-federal lands. If there is a low effect on endangered species, then a Habitat Conservation Plan (HCP) can be developed. There is a fee for filing the HCP but the process can be streamlined and takes about a year.

Protocol surveys for the desert species will not be conducted prior the Biological Assessment being submitted. Protocol surveys will be conducted prior to construction.

5. Avian Risk Assessment

USFWS has Condor GPS data that they will provide to help with the Avian Risk Assessment.

Swan diverters should be used and mid ridge will be better for the condors.

A condor fund has been set up to help purchase transmitters. This is a nonprofit conservation and tax-deductible for agencies that contribute.

USFWS contact information for condor data:

Hi Chris,

I received your contact information from Nancy Sandburg. I'm a biologist with Power Engineers working on the proposed Barren Ridge Renewable Transmission Project (BRRTP) for the City of Los Angeles of Water and Power. BRRTP spans a distance of approximately 75 miles from the Mojave Desert south to the San Fernando Valley. The project is located within northwestern Los Angeles County and southwestern Kern County. The study area measure approximately 1,280 square miles. Within this study area several routing possibilities have been identified that traverse through the Antelope Valley, across Angeles National Forest, and public lands located in the Mojave Desert. Please refer to the enclosed map for the location of the alternatives currently being considered.

We are currently conducting an Avian Risk Assessment on all the routing possibilities. Nancy indicated that you would be able to provide GPS data for condors within our project area. Any information that you can provide that will help in our Avian Risk Assessment analysis would be appreciated.

Subject

Barren Ridge Renewable Transmission Project Biology Survey Update

Ashleigh and Della,

I just wanted to send you a quick update on the progress of the survey work for BRRTP. Survey work started July 21 for the desert habitat assessment.
Crews consisting of 4 biologists walked transects along the 150 feet wide to 500 feet wide corridor as right-of-entry access is allowed. Survey crews started from the north and have completed Link A and B. They will continue surveying Link C this week. The biologists have documented natal dens, one badger den and active desert tortoise area along Link A (one live tortoise).

A team of 2 biologists have completed the detailed desert habitat assessment for Link D, E, F, G, and H. A good portion of these links consist of agriculture and/or urban environment, which restricted the survey area and species to be present. The team did a mixture of walking/driving sections and surveys were restricted to the ROW. We did not physically enter private lands.

Starting August 18 the bat surveys will start and we have an anticipated start date of September for the focused non-breeding amphibian surveys.
Also the avian risk assessment crew will be in the field for a second round of surveys during the fall migration period.

Please let me know if you have any questions or concerns.

Thank You,

Vanessa

Barren Ridge Renewable Transmission Project

California Department of Fish and Game

Contact History

Vanessa Gutierrez 2729

From: Vanessa Gutierrez 2729
Sent: Wednesday, April 02, 2008 3:59 PM
To: [redacted]
Subject: Biology contact for the Barren Ridge Renewable Transmission Project

Attachments: Project Location Map.pdf; Barren Ridge Species Table.pdf

Dan,

We spoke briefly yesterday about the Barren Ridge Renewable Transmission Project and you being the possible Department of Fish and Game contact for this project. Below is a brief description of the project and I've also attached a map and species table for you to review. The table includes all state, federal and Forest Service listed species that we've identified as potentially occurring within the project area. I'll be in contact with you in the next few days to talk about the species and confirm our list. Thank you for your prompt attention. If you have any questions or need additional information, please call me at [redacted].

The City of Los Angeles Department of Water and Power (LADWP), is proposing the Barren Ridge Renewable Transmission Project to access clean, renewable resources in the Tehachapi Mountain and Mojave Desert areas, and improve reliability and upgrade transmission capacity. The Forest Service, BLM, and LADWP will prepare a joint Environmental Impact Statement/Environmental Impact Report (EIS/EIR) for the Barren Ridge Renewable Transmission Project. The Forest Service, BLM, and LADWP have identified preliminary alternatives to the proposed project.

The Barren Ridge Renewable Transmission Project spans a distance of approximately 75 miles from the Mojave Desert south to the San Fernando Valley. The project is located within northwestern Los Angeles County and southwestern Kern County. The project study area is generally defined by the following limits: the northern boundary is the southern slopes of the Tehachapi Mountains, eastern boundary parallels State Route 14, southern boundary generally parallels the Santa Clara River, and the western boundary parallels Interstate 5. The study area measures approximately 1,280 square miles. Within this study area several routing possibilities have been identified that traverse through the Antelope Valley, across Angeles National Forest, and public lands located in the Mojave Desert. Please refer to the enclosed map for the location of the alternatives currently being considered.

Notice of Preparation of a Draft Environmental Impact Report for the Barren Ridge Renewable Transmission Project Los Angeles County

Dear Mr. Holloway:

The California Department of Fish and Game (Department) has reviewed the above-referenced Notice of Preparation (NOP), for a Draft Environmental Impact Report relative to impacts to biological resources. The project proposes to access clean, renewable resources in the Tehachapi Mountain and Mojave Desert areas. Proposed work consists of construction of a 230 kilovolt (kV) transmission line from the existing Barren Ridge Switching Station to Haskell Canyon on double circuit structures; add a 230 kV circuit on existing double circuit structures from Haskell Canyon to the Castaic Power Plant; upgrade the existing Owen Gorge-Rinaldi 230 kV Transmission Line with larger capacity conductors between the Barren Ridge Switching Station and Rinaldi Substation; and construction of a new electrical switching station within Haskell Canyon near the southern boundary of the Angeles National Forest.

Biologists from Power Engineers have been coordinating with Department staff regarding potential species that may be impacted along the proposed transmission line alignments. The Department appreciates the opportunity to work with biologists early in the planning process. In general Department staff recommends that California Natural Diversity Database (CNDDB) element occurrences be used along with current sensitive species range and habitat use information to determine potential for sensitive species occurrence to be as inclusive as possible when considering potential impacts and survey needs.

The California Wildlife Action Plan, a recent Department guidance document, identified the following stressors affecting wildlife and habitats within the project area: 1) growth and development; 2) water management conflicts and degradation of aquatic ecosystems; 3) invasive species; 4) altered fire regimes; and 5) recreational pressures. The Department looks forward to working with Los Angles Department of Water and Power (LADWP) to minimize impacts to fish and wildlife resources with a focus on these stressors.

The Department recommends the development of an endowment for habitat restoration to be used in the general project area on conservation lands as mitigation for long-term impacts the project has on nesting raptors and other nesting migratory birds. Nesting birds are occasionally impacted during construction and maintenance of transmission lines. These funds would be held in an account with the California Wildlife Foundation and made available through a grant program for projects that enhance and restore nesting habitat for raptors and neotropical migrants within the general project area. The Department recommends further developing this concept with LADWP to determine the feasibility and the potential to assess mitigation. The Department understands the need to enhance our power grid for southern California, but must also address the long term impacts to wildlife resources caused by above ground transmission and distribution lines. This proposed concept will help to streamline permitting as well as ensure that impacts caused by the project are mitigated.

To enable Department staff to adequately review and comment on the proposed project we recommend the following information, where applicable, be included in the Draft Environmental Impact Report:

1. A complete, recent assessment of flora and fauna within and adjacent to the project area, with particular emphasis upon identifying endangered, threatened, and locally unique species and sensitive habitats (Attachment 1).

    a. A thorough recent assessment of rare plants and rare natural communities, following the Department's Guidelines for Assessing Impacts to Rare Plants and Rare Natural Communities.

    b. A complete, recent assessment of sensitive fish, wildlife, reptile, and amphibian species. Seasonal variations in use of the project area should also be addressed. Recent, focused, species-specific surveys, conducted at the appropriate time of year and time of day when the sensitive species are active or otherwise identifiable, are required. Acceptable species-specific survey procedures should be developed in consultation with the Department and U.S. Fish and Wildlife Service.

    c. Rare, threatened, and endangered species to be addressed should include all those which meet the California Environmental Quality Act (CEQA) definition (see CEQA Guidelines, Section 15380).

    d. The Department's Biogeographic Data Branch in Sacramento should be contacted at (916) 322-2493 to obtain current information on any previously reported sensitive species and habitats, including Significant Natural Areas identified under Chapter 12 of the Fish and Game Code. Also, any Significant Ecological Areas SEAs) or Environmentally Sensitive Habitats (ESHs) or any areas that are considered sensitive by the local jurisdiction that are located in or adjacent to the project area must be addressed.

    e. Desert kit fox (*Vulpes macrotis arsipus*) are known to occur within portions of the project vicinity and should be included in the species analysis. The California Code of Regulations (CCR) Chapter 5 § 460 states that, "Fisher, marten, river otter, desert kit fox and red fox may not be taken at any time." We recommend that you contact the Department for guidance on take avoidance measures for the desert kit fox.

2. A thorough discussion of direct, indirect, and cumulative impacts expected to adversely affect biological resources, with specific measures to offset such impacts. This discussion should focus on maximizing avoidance, and minimizing impacts.

    a. CEQA Guidelines, Section 15125(a), direct that knowledge of the regional setting is critical to an assessment of environmental impacts and that special emphasis should be placed on resources that are rare or unique to the region.

    b. Project impacts should also be analyzed relative to their effects on off-site habitats and populations. Specifically, this should include nearby public lands, open space, adjacent natural habitats, and riparian ecosystems. Impacts to and maintenance of wildlife corridor/movement areas, including access to undisturbed habitat in adjacent areas are of concern to the Department and should be fully evaluated and provided. The analysis should also include a discussion of the potential for impacts resulting from such effects as increased vehicle traffic, outdoor artificial lighting, noise and vibration.

c. A cumulative effects analysis should be developed as described under CEQA Guidelines, Section 15130. General and specific plans, as well as past, present, and anticipated future projects, should be analyzed relative to their impacts on similar plant communities and wildlife habitats.

d. Impacts to migratory wildlife affected by the project should be fully evaluated including proposals to remove/disturb native and ornamental landscaping and other nesting habitat for native birds. Impact evaluation may also include such elements as migratory butterfly roost sites and neo-tropical bird and waterfowl stop-over and staging sites. All migratory nongame native bird species are protected by international treaty under the Federal Migratory Bird Treaty Act (MBTA) of 1918 (50 C.F.R. Section 10.13). Sections 3503, 3503.5 and 3513 of the California Fish and Game Code prohibit take of birds and their active nests, including raptors and other migratory nongame birds as listed under the MBTA.

e. Impacts to all habitats from City or County required Fuel Modification Zones (FMZ). Areas slated as mitigation for loss of habitat shall not occur within the FMZ.

f. Proposed project activities (including disturbances to vegetation) should take place outside of the breeding bird season (February 1- September 1) to avoid take (including disturbances which would cause abandonment of active nests containing eggs and/or young). If project activities cannot avoid the breeding bird season, nest surveys should be conducted and active nests should be avoided and provided with a minimum buffer as determined by a biological monitor (the Department recommends a minimum 500-foot buffer for all active raptor nests).

3. A range of alternatives should be analyzed to ensure that alternatives to the proposed project are fully considered and evaluated. A range of alternatives which avoid or otherwise minimize impacts to sensitive biological resources including wetlands/riparian habitats, alluvial scrub, coastal sage scrub, Joshua tree woodlands, etc. should be included. Specific alternative locations should also be evaluated in areas with lower resource sensitivity where appropriate.

a. Mitigation measures for project impacts to sensitive plants, animals, and habitats should emphasize evaluation and selection of alternatives which avoid or otherwise minimize project impacts. Compensation for unavoidable impacts through acquisition and protection of high quality habitat elsewhere should be addressed with offsite mitigation locations clearly identified.

b. The Department considers Rare Natural Communities as threatened habitats having both regional and local significance. Thus, these communities should be fully avoided and otherwise protected from project-related impacts (Attachment 2).

c. The Department generally does not support the use of relocation, salvage, and/or transplantation as mitigation for impacts to rare, threatened, or endangered species. Department studies have shown that these efforts are experimental in nature and largely unsuccessful.

4. A California Endangered Species Act (CESA) Permit must be obtained, if the project has the potential to result in "take" of species of plants or animals listed under CESA, either during construction or over the life of the project. CESA Permits are issued to conserve, protect, enhance, and restore State-listed threatened or endangered species and their habitats. Early consultation is encouraged, as significant modification to the proposed project and mitigation measures may be required in order to obtain a CESA Permit. Revisions to the Fish and Game Code, effective January 1998, require that the Department issue a separate CEQA document for the issuance of a CESA permit unless the project CEQA document addresses all project impacts to listed species and specifies a mitigation monitoring and reporting program that will meet the requirements of a CESA permit. For these reasons, the following information is requested:

   a. Biological mitigation monitoring and reporting proposals should be of sufficient detail and resolution to satisfy the requirements for a CESA Permit.

   b. A Department-approved Mitigation Agreement and Mitigation Plan are required for plants listed as rare under the Native Plant Protection Act.

5. The Department opposes the elimination of watercourses (including concrete channels) and/or the canalization of natural and manmade drainages or conversion to subsurface drains. All wetlands and watercourses, whether intermittent, ephemeral, or perennial, must be retained and provided with substantial setbacks which preserve the riparian and aquatic habitat values and maintain their value to on-site and off-site wildlife populations. The Department recommends a minimum natural buffer of 100 feet from the outside edge of the riparian zone on each side of a drainage.

   a. The Department requires a Streambed Alteration Agreement (SAA), pursuant to Section 1600 et seq. of the Fish and Game Code, with the applicant prior to any direct or indirect impact to a lake or stream bed, bank or channel or associated riparian resources. The Department's issuance of a SAA may be a project that is subject to CEQA. To facilitate our issuance of the Agreement when CEQA applies, the Department as a responsible agency under CEQA may consider the local jurisdiction's (Lead Agency) document for the project. To minimize additional requirements by the Department under CEQA the document should fully identify the potential impacts to the lake, stream or riparian resources and provide adequate avoidance, mitigation, monitoring and reporting commitments for issuance of the Agreement. Early consultation is recommended, since modification of the proposed project may be required to avoid or reduce impacts to fish and wildlife resources.

Thank you for this opportunity to provide comment. Please contact Mr. Dan Blankenship, Staff Environmental Scientist, [redacted] if you should have any questions and for further coordination on the proposed project.

Sincerely,

Edmund J. Pert

MEETING MINUTES

SUBJECT:	Biology Meeting			
MEETING DATE:	05/30/08, 2pm		LOCATION:	Call in - 877-797-2663, 2710#
PROJECT NAME:	BRRTP		PROJECT #:	113807
PREPARED BY:	Vanessa Gutierrez			
TO:	LADWP	BLM	CDFG	POWER
	Charles Holloway Nadia Dale Mark Sedlacek	Linn Gum Bob Parker	Daniel Blankenship Annette Tenneboe	Mike Strand Vanessa Gutierrez Jim Jensen

ATTENDEES:

Charles Holloway, Nadia Dale, Linn Gum, Bob Parker, Daniel Blankenship, Annette Tenneboe, Mike Strand, Vanessa Gutierrez

AGENDA ITEMS:

1. **Biological Survey Needs and Schedule**

USFW has suggested a zig-zag survey approach, which would involve walking the entire area in a pattern for animal surveys in the desert areas. POWER prefers this approach to a protocol-level survey for all species of concern, although it would be limited to a 500-ft. corridor and not the protocol surveys. This method was proposed because the Project does not have a known footprint.

The project has identified alternatives for the corridors; however, BRRT does not have finalized centerlines. LADWP will be working to refine the centerline, design and tower access roads. Until this process is complete we don't have specific areas that will be impacted.

No new roads with exception of alignment that follows aqueduct. Foundation for towers will be impacts sites, have flexibility with towers and can avoid sensitive areas.

Annette (CDFG) concerned with survey approach and ability to cover all species adequately. CDFG also indicated that the approach suggested by USFWS is a detailed habitat assessment approach rather than protocol surveys.

This approach would be a detailed habitat assessment approach with the survey work consisting of walking the entire, accessible, corridor. The survey work would need to stay within the LADWP easements for the aqueduct and transmission lines.

LADWP indicated that it is 200 / 150 feet easement.

The information gathered will help verify and perfect the habitat assessment that has been completed and this survey data will be utilized in the Draft EIR and Biological Assessment.

MEETING MINUTES

CDFG agreed with the approach and indicated that during this intensive habitat assessment the Mohave ground squirrel, burrowing owl and Swainson's hawk should be included in the habitat assessment. LADWP agrees that the habitat assessment surveys should include all these species.

CDFG recommends that we look for habitat south of Highway 58 for the Mohave ground squirrel.

An avian risk assessment will also be conducted along all alignments and this survey work will start June 9.

2. Project Schedule and Future Survey Needs

LADWP anticipate that the EIR will be certified in February 2010 and construction starting in 2011. Preconstruction surveys will be done at this time.

3. CDFG Contact Information

Dan is the CDFG contact for Region 5 and Annette is the contact for Region 4. Both agree that there should one lead for the BRRT Project. Dan has indicated that he will be the lead for this project and will coordinate with Annette

Subject: Re: Barren Ridge Renewable Transmission Project Desert HabitatSurveys

Hi Vanessa, Hope all is going well. I have double checking with Annette and running it by Scott Harris. I will let you know asap. Thanks, Dan

>>> [redacted] 7/9/2008 8:59 AM >>>
Hi Dan,

We are gearing up to start the desert habitat assessment survey work for the Barren Ridge Renewable Transmission Project (BRRTP). I wanted to touch base with you before we start this survey work and verify that our approach is consistent with what we discussed and agreed upon during our May 30 meeting with Annette and LADWP.

POWER will conduct habitat delineation surveys for sensitive desert species along the desert portion of the BRRTP. The intent is to review a 500 feet wide corridor and walk transects along the 150 feet wide to 500 feet wide corridor as right-of-entry access is allowed. The surveys are not intended to be conducted by physically entering private lands where entry permission is not documented.

The goal of the survey will be to document any observed sensitive wildlife species and evaluate habitat for suitable characteristics to support state or federal protected species. The biologists will walk linear transects that meander through the habitat to accomplish a comprehensive cover of the survey area. It is not intended that the surveys be a 100-percent cover or include protocol level surveys. The goal will also be to accurately map quality of habitat by one-tenth mile increments for the proposed alternative project routes. The biologists will map any observed sign and potential habitat for the desert tortoise and Mohave ground squirrel that are typically active during the daylight at higher temperatures. Additionally the biologists will map any observed potential kit fox natal dens and any potential burrowing owl ground burrows. The biologists will also map clusters and some single Joshua trees and distinct ephemeral washes.

Please let me know if you have questions or concerns. We will be starting the field work July 21.

Thank You,

Vanessa

Dan and Annette,

I just wanted to send you a quick update on the progress of the survey work for BRRTP. Survey work started July 21 for the desert habitat assessment. Crews consisting of 4 biologists walked transects along the 150 feet wide to 500 feet wide corridor as right-of-entry access is allowed. Survey crews started from the north and have completed Link A and B. They will continue surveying Link C this week. The biologists have documented natal dens, one badger den and active desert tortoise area along Link A (one live tortoise).

A team of 2 biologists have completed the detailed desert habitat assessment for Link D, E, F, G, and H. A good portion of these links consist of agriculture and/or urban environment, which restricted the survey area and species to be present. The team did a mixture of walking/driving sections and surveys were restricted to the ROW. We did not physically enter private lands.

Starting August 18 the bat surveys will start and we have an anticipated start date of September for the focused non-breeding amphibian surveys. Also the avian risk assessment crew will be in the field for a second round of surveys during the fall migration period.

Please let me know if you have any questions or concerns.

Thank You,

Vanessa

Hello All
Here is the Forest Biologist's comments to the Statement of Work for the bio surveys

As you can see, there is concern about the way field survey's were described. My understanding is that SCE did complete field surveys for TRTP
- but when we meet w/ Aspen, SCE, and CPUC as a group - we can validate.

BarrenRidge-Castaic Bio. surveys

Hi Marian,

In response to the Barren Ridge-Castaic Transmission Project Sensitive Plant habitat Surveys Spring 2008 memo received yesterday on February 12, 2008, we have the following concerns with the Barren Ridge-Castaic Transmission Project proposed surveys for biological resources.

General:

1. Wildlife and botanical field surveys need to be completed for analysis within the Biological Evaluation and Biological Assessment (BEBA) and the EIR/EIS. Field surveys are not considered optional.

Note: Power Engineers stated that field surveys were "optional", and that habitat mapping will be conducted the first year, with survey work to be conducted in the second year, after completion of the draft EIR/EIS. If this action is taken, Jeopardy should be assumed for potential TES species in the BA and EIR/EIS.

2. Surveys and habitat assessments should be conducted on all alternatives. Five field days of survey time as proposed by Power Engineers is not considered sufficient for flora or fauna surveys.

POWER Engineers needs to provide the following:

Flora:

1) A vegetation map based on Sawyer-Keeler Wolf 'A Manual of California Vegetation'. This includes all including temporary roads, permanent roads, splicing stations, tower locations, staging areas, helicopter landing areas, etc. These surveys will be completed for all alternatives.

2) A floristic survey following California Native Plant Society (CNPS) Guidelines for all including temporary roads, permanent roads, splicing stations, tower locations, staging areas, helicopter landing areas, etc. These surveys will be completed for all alternatives. These guidelines can be found at the following web site: www.cnps.org/cnps/rareplants/pdf/cnps_survey_guidelines.pdf

3) USDA Forest Service TES Plant Survey Field Forms and TES Plant Element Occurrence Field Forms are needed in lieu of filling out California Natural Diversity Database (CNDDB) forms. When completed they will be returned to the Forest Botanist.

4) Protocol level surveys if any suitable habitat is present for federally listed species.

5) GPS coordinates and maps of Invasive species.

6) A final report to include

- Vegetation map of proposed route and all alternatives
- A map of any invasive species
- Completed out USDA Forest Service TES Plant Survey Field Forms and TES Plant Element Occurrence Field Forms
- A complete floristic list of all plant found during focused surveys
- Results of the surveys

Fauna:

6) USFWS and USFS protocol surveys for habitat suitable for threatened endangered and sensitive species to be conducted on all affected habitat.

7) A risk assessment for potential power line caused mortality/interference for the California condor and birds of prey for all alternatives.

8) GPS coordinates on observed TES and MIS fauna provided electronically utilizing a provided USFS (NRIS) form for all alternatives.

9) Quantitative data on habitat change (vegetative and seral communities in acres or linear area) as a result of the proposed project will be listed and used to address impacts to TES and MIS habitat and species. A BEBA based on site surveys for threatened, endangered and sensitive species on all project affected areas (BEBA template available from the ANF).

10) A management indicator species report (MIS) prior to a signed Decision memo. The MIS will include quantitative data on affected habitat, and this data will be used to assess impacts on these species (MIS template available from the ANF).

11) Within two weeks of project implementation, nesting bird surveys will be conducted at active project sites.

12) Final field survey reports to contain:

- Survey results for species
- GPS coordinates in electronic format and recorded on USFS forms for TES species
- Risk analysis on power line collisions and interference
- Habitat acres for TES and MI species to be affected by proposed alternatives and seral or type conversion expected changes

If you have any questions, please let me know.

Thanks!

MEETING MINUTES

SUBJECT:	BIOLOGICAL RESOURCES CONFERENCE CALL MEETING		
MEETING DATE:	02-22-2008	*LOCATION:*	Conference Call – Anaheim Office
PROJECT NAME:	BARREN RIDGE-CASTAIC TRANSMISSION LINE PROJECT	*PROJECT #:*	113807
PREPARED BY:	Nancy Abbott		
ATTENDEES:	Marian Kadota, Linn Gumm, Chuck Holloway, Nadia Dale, Mike Strand, Jim Jensen, Vanessa Gutierrez, Bob Parker, Janet Nickerman, Nancy Sandburg, Nancy Abbott		

Reconnaissance Biological Surveys

- POWER made some modifications to the Habitat Assessment work plan by removing the "optional" task. All comments from FS were not addressed, as that was the purpose of the call to discuss.
- Mike S. explained that POWER's suggested approach is to conduct the habitat assessment right away on all alternatives. This would be done using existing vegetation data that consists of FS data covering the Angeles NF and GAP data covering the remainder of the project study area. The data would be "refined" as necessary using aerial photography and by conducting field reconnaissance level surveys by biologists and botanists. These would not be focused surveys but would rather be used to check and further refine the vegetation data used to determine habitat types that would support sensitive plants or animals. If a protected plant or animal would have a potential for being within the alternative corridors, surveys methods and timeframes would be identified. From that point a determination would be made as to whether focused plant or animal surveys would be conducted during spring 2008.
- FS biologists had concern with this approach. FS suggested conducting focused sensitive plant surveys this spring (2008) on all alternatives being considered. This was their understanding from our kick off meeting. Aspen is conducting focused surveys on all alternatives for TRTP. Need this level of data to adequately determine impacts and to conduct consultation with USFWS.
- POWER explained how this process would work but there was still some concern over the approach and particularly not taking advantage of this years good rain season. Discussion over different approaches continued. Chuck said LADWP would agree to conduct the sensitive plant surveys this spring and approved the habitat assessment work plan submitted by POWER. During the habitat assessment POWER will develop a scope of work and cost estimate for conducting the focused plant surveys this spring.
- FS requests that Noxious Weed Surveys are conducted in addition to the plant surveys this year.
- Vanessa will identify the needs for the surveys and available resources.
- POWER will work with GANDA to conduct plant surveys this Spring 2008.
  - ➢ Plan to be on the ground March 15 for plant surveys and will discuss and review protocols during the March 12th contractor meeting for consistency with other SCE projects.
  - ➢ Janet identified that additional FS forms will be needed.
  - ➢ Bob indicated that West Mojave has specific survey requirements that POWER should be aware of.
- Nancy indicated, in addition to her email comments, that a risk assessment for potential power line caused mortality / interference for the California condor and birds of prey will need to be conducted.

MEETING MINUTES

- Jim identified that for this Project we are assuming presence of sensitive animal species for the DEIR/EIS if the habitat is present within our corridors.
- Marian will talk to Sara regarding the NEPA vs. CEQA process. Also concerns with Antelope/Pardee lawsuit and will send email about the 9th circuit law.

ACTION ITEMS:

1. Vanessa to set up conference call to discuss progress of the surveys (Due 2/22/08)
2. Justin and Chuck locate the GIS files of Alignments from SCE or Aspen (Due asap)
3. Marian to send email regarding Antelope/Pardee lawsuit. (Due asap)

BRRTP Biological Survey Meeting

Date: March 24, 2008
Location: Arcadia Office
Attendees: Nancy Sandburg. Marian Kadota, Vanessa Gutierrez, Mike Strand

- Amphibian Surveys : Nancy Sandburg discussed need to survey Haskell Canyon for Red Legged Frogs
- RCA's need guard structures to protect riparian/ streams of significance
  - If a "negative effect" to RCA's will require a Forest Plan Amendment
- Micro-pile foundations – need to control water used for lubricant for drilling
  - reluctant for geotech testing
  - discuss with LADWP if they will use micro pile or will the use traditional foundations

- Forest Service has a GIS form to record species locations. Nancy Sandburg will provide forms.
- Forest Service indicated that there needs to be an estimate of acres of habitat (temp./perm.) effected by project
- MIS reports if indicator species ranges are within the corridors.
  - Spotted Owl Survey
- Wildlife – the 20% sampling method will be used on the tortoise and squirrel. Need to discuss this approach with Fish and Wildlife Service
- Migrating Birds: need to prepare a risk assessment
  - Look at all nests for migrating birds
  - Need to perform pre-construction survey 1 week before construction

- I-5 pipeline
  - Currently re-burring pipes exposed from 2005 landslides
  - Forest Service may have some bio data that can be used
  - Forest to provide BA/BO to POWER

MEETING MINUTES

SUBJECT:	Biology Meeting		
MEETING DATE:	May 8, 2008	LOCATION:	LADWP Office
PROJECT NAME:	BRRTP	PROJECT #:	113807
PREPARED BY:	Vanessa Gutierrez		

TO:	LADWP	USFS	BLM	POWER
	Chuck Holloway	Marian Kadota	Linn Gum	Jim Jensen
	Mark Sedlacek	Katie VinZant		Mike Strand
	Nadia Dale			Karen Cadavona
				Vanessa Gutierrez
				Ann Howald (GANDA)

ATTENDEES:

Chuck Holloway, Nadia Dale, Katie VinZant, Vanessa Gutierrez, Ann Howald

AGENDA ITEMS:

1. **Botany Surveys**
    - FS in agreement with locations that Katie has picked to survey
    - Link J and Link I are complete.
    - The southern portion of Link G is complete
    - Link H to be completed at the end of the month (May)
    - Northern portion of G to be surveyed at the end of May

2. **Seed Collection**
    - FS – no collection of seed this year (2008)
    - Collection will need to happen pre-construction
    - Seeds need to be local and native

3. **Herbicide**
    - Herbicide treatment is more cost effective than manual
    - Chuck concerned with downstream effects
    - FS will need a defined area to recommend treatment
    - FS to look into protocol for herbicide use in the Forest
    - LADWP will look into what is currently being done for transmission maintenance

MEETING MINUTES

SUBJECT:	Biology Meeting		
MEETING DATE:	October 22, 2008	LOCATION:	USFS Arcadia Office
PROJECT NAME:	BRRTP	PROJECT #:	115244
PREPARED BY:	Vanessa Gutierrez		

TO:	LADWP	USFS	BLM	POWER
	Chuck Holloway	Cindy Whelan	Linn Gum	Jim Jensen
	Mark Sedlacek	Justin Seastrand		Mike Strand
	Nadia Dale	Nathan Sill		Karen Cadavona
		Katie VinZant		Vanessa Gutierrez

ATTENDEES:

Cindy Whelan, Nathan Sill, Chuck Holloway, Nadia Dale, Mike Strand, Jim, Jenson, Vanessa Gutierrez

AGENDA ITEMS:

1. **Biological Surveys**
   Surveys finished in September 2008, working on survey reports, reports are in draft being reviewed by POWER; Vanessa handed out survey report schedule
   a. Strand described the development of alternatives and why bio surveys were conducted this year on all segments within a 500’ width.
   b. Vanessa provided a brief overview of the biological surveys conducted for the project.
   c. Re-route around Green Valley will be dropped from consideration.

2. **Survey Reports**
   Nathan expressed some concern about the schedule and having FS staff available to review reports in November – December.

3. **Riparian Conservation Areas**
   a. Power is in the process of completing the mapping
   b. They are exclusion areas
   c. Known occurrence areas (1-mile buffer) can be reduced by identifying ridgelines that would limit or “cut off” the buffer
   d. If we have activities that disturb/remove riparian vegetation, then it would require a Plan Amendment
   e. Did the NOI include language regarding a PA? No, but not a problem as the EIS will serve as the review document for the PA and the project.
   f. Will the West Wide Corridor EIS/PA amend the Angeles Plan so it would eliminate need for a PA for the BRRTP? Unknown, we will need to look into this.

g. Need to discuss and define mitigation, including replacement for habitat loss. EIS will define the mitigation and will include estimates of acres of impact. The actual will come once the decision is made and designed and included in POD.

4. **Impact Assessment**
   a. Discussion of impact assessment; focusing on 1/10-mile impact "take-offs" as a way to document and report the impacts for all alternatives. This will be used to develop and compare the alternatives. The plan is to have a 500' "impact corridor" that will be used to identify impacts based on the resource (bio) inventory. Mitigation will be used to reduce impacts as necessary. Nathan expressed a desire from the FS to have design so impacts can be identified at a specific location. Strand explained that our methodology is developed to balance this need with the constraints of developing a transmission line. If decision is completed within the EIS, we will have a greater chance to require a supplemental to the EIS as design will change as it's developed. Our methodology is designed to balance these 2 issues, need for specific impacts vs. no design. Nathan thought this made sense. The detailed design of structures and roads will be identified prior to Notice to Proceed within the Communication Plan and POD.

5. **Ground Disturbance Analysis**
   Mike provided a brief overview.

OFF-AGENDA ITEMS:

USFWS Consultation

- No agreement in place between FS and BLM on who takes land for consultation, although the BLM has verbally agreed to take lead for private lands and thus for entire project.
- Nathan thinks the MOU states FS would take lead for Forest although this is not ideal; would rather have one agency in lead role.
- USFWS needs to agree with approach. We have had several meetings with FWS to discuss approach and they have agreed although not officially in writing or with an agreement.
- Nathan will talk with Della (USFWS) to confirm approach that one agency will take lead on the entire project.

ACTION ITEMS:

Item	Action	Responsibility	Due Date
West Wide Corridor	Investigate impact on PA for BRRTP	POWER	
USFWS Consultation	Discuss and confirm agency lead	Nathan

Subject: RE: BRRTP
Attachments: Nest008.JPG

Hi,
We had a nice ride down ROW road- a bit smoky though. I took a photo of these two towers- the one on the left has a nest in it (realized I'd forgotten which ones are LADWPs). Poked around underneath and didn't see any pellets like a raven would produce. Didn't see any birds, but it's good sized like a red-tailed hawk. Kind of late for nesting but we did see a redtail in the area. Did your crews see any birds?

We got UTMs (NAD 83) at:

398226
3889916

(See attached file: Nest008.JPG)

I guess we'll see you up here towards the end of July.

Subject: Mojave Ground Squirrel Conservation Area (MGSCA)

Hi, Vanessa, et.al.;

Just a quick line to clarify some information from Thursday's ID Team meeting with us here at the BLM.

I know there was some discussion regarding the mojave ground squirrel (MGS) and possible impacts to this project because of the existence of the MGSCA designation found within the West Mojave Plan (WEMO).

Review of the WEMO, particularly map A which shows the acres subject to the restrictions associated with the MGSCA, conclusively shows the area of interest for the BRRTP is not contained within the lands designated as MGSCA. So, while we may need to provide some information/discussion regarding the MGS, we don't have to worry about the restrictions enumerated in the WEMO placed on development within the MGSCA.

Should you have any questions regarding this matter, please contact me at your earliest convenience.

MEETING MINUTES

SUBJECT: Steering Committee

MEETING DATE: 02-27-2008

LOCATION: Conference Call (877) 797-2663, 2710#

PROJECT NAME: Barren Ridge-Castaic Transmission Line Project

PROJECT #: 113807

PREPARED BY: Nancy Abbott

TO:

LADWP	Forest Service	BLM	POWER
Chuck Holloway	Justin Seastrand	Linn Gum	Jim Jensen
Mark Sedlacek	Marian Kadota		Michael Strand
Nadia Dale			Karen Cadavona

ATTENDEES:

LADWP: Nadia Dale, Chuck Holloway, Mark Sedlacek **FS:** Marian Kadota, Justin Seastrand, Nancy Sandberg, Janet Nickerman **BLM:** Linn Gum, Bob Parker **POWER:** Jim Jensen, Mike Strand, Karen Cadavona, Vanessa Gutierrez, Nancy Abbott **Garcia & Associates** (sub-consultants): Dave Kelly, Samantha Hillarie.

AGENDA ITEMS:

1. BIOLOGICAL RESOURCES

POWER is conducting a habitat analysis using GIS data to determine what surveys need to be conducted based on the habitat. In 2-3 weeks, POWER and Garcia & Associates will conduct field surveys where habitats are present. POWER Protocol surveys will be conducted where needed in April/May. On March 12th meeting at LADWP, biologists will discuss survey requirements.

Marian is still concerned about the EIS being too general in its biology assessment. Antelope-Pardee (A-P) is currently dealing with this problem. The CEQ group message is that an EIS supplement is needed. FS generally does more site specific analysis in comparison to the one proposed by LADWP. Chuck states that transmission lines are different than most projects since it's not confined to a small area like timber sales and are long linear projects. For transmission lines, siting only occurs when the final alignment is determined; doing siting for all alternatives is not realistic. During construction, there are site specific areas for wildlife and fauna that are not disturbed and avoided (February – August). Marian is not comfortable assuming presence and waiting for an appropriate time. From her experience, Fish & Wildlife does not like to make decisions on general assessment.

POWER will conduct a habitat assessment to narrow down areas that need to be surveyed. All Threatened & Endangered (T&E) species will be assessed on Federal Land. (Cannot conduct field surveys on private land where access is not granted.) Endangered Species Act requires an equal analysis for all alternatives. Protocol surveys need to be done even on non-Federal lands.

MEETING MINUTES

A determination will be made to do either a Section 7 or Section 10. Before the Draft EIR/EIS is published a preferred alternative will be identified.

Jim notes the two issues of A-P. (1) In the EIR/EIS no improvements were to occur in the riparian conservation areas. However, 3 towers were located in the conservation areas and could not be avoided. RCA could have an adverse affect. (2) The mid-slope changes minimized the number of tower sites, but it created longer pulling and slicing spans. Therefore, the impacts from pulling and slicing created a much greater ground disturbance.

Marian suggest a two tiered document—a general assessment and then a site specific analysis. Jim explains that a NEPA EIS decision can be made even with a general biology assessment. However, a decision does not grant a project to proceed. A ROD and all permits are required. Also, a notice to proceed with construction must be granted. All micro-siting, consultations, and protocol surveys need to be done beforehand. The ROD will also have an agreement on centerline and ROW in quarter sections.

				Vanessa Gutierrez

ATTENDEES:

Chuck Holloway, Nadia Dale, Mark Sedlacek, Marian Kadota, Linn Gum, Jim Jensen, Vanessa Gutierrez

COMMENTS ON PREVIOUS ACTION ITEMS:

Vanessa to meet with Fish & Wildlife Service – DONE
Karen to do agenda for Purpose & Need Workshop – DONE
Power Screening Criteria – STILL BEING WORKED ON
Community Working Groups – CANCELLED

Mark S. updated the committee and City Council approved contract with POWER and currently waiting for signatures.

AGENDA ITEMS:

1. Biological Surveys

- Ashleigh Blackford of the Ventura Fish and Wildlife Office responded to POWER's request for survey protocols regarding the desert tortoise. USFWS has directed us to conduct surveys using a zigzag approach to determined suitability and incidental observations along the corridors within potential habitat. Permission has also been given to survey outside the survey period window.
- Botany crew will survey Corridor H next week (May). Amphibian, bird, avian risk assessment, desert tortoise and plants survey will be starting up again in June.
- Although a 100% survey is preferred, it cannot be done at this time due to steepness of area and extremely dense chaparral.
- FS requested that botany crews survey down slope from the SCE line on Corridor H as up slope will not be approved. Marian was in field last week and saw lilies in the corridor
- LADWP is working on getting another set of keys for the biology field crew.
- FS wants to know how alternatives are being dealt with that are going around the Green Valley area possibly outside the corridor. POWER is aware and reviewing area fire road near "roadless" area.

ATTENDEES:

Nadia Dale, Marian Kadota, Linn Gum, Jim Jensen, Mike Strand, Karen Cadavona, Vanessa Gutierrez

AGENDA ITEMS:

1. Biological Surveys

- Fish and Game Meeting

  CDFG meeting scheduled for Friday, 5/30 at 2pm to clarify Desert Tortoise protocol survey due to the discrepancies between CDFG and FW. Vanessa will be sending meeting invitations to Marian and Linn. Marian states there will be no biologist available or on-call this week.

- Survey Schedule

  Botanists are currently spending two weeks along Alternative H.
  Amphibian protocol to begin 6/18
  Spotted Owl and Avian risk to begin 6/9
  The surveys will overlap during the month of June on a 2 weeks on/2 weeks off rotating schedule.

- Antelope-Pardee line alignment clarification issues

  The Antelope-Pardee alignment is off for towers 33-37. Katie made the discovery of the incorrect alignment. Marian noted that 6 towers were moved due to geotech conditions (unstable soils), and the new locations are currently staked. Should POWER identify tower locations by GIS? Marian states that the area is geologically unstable, very steep and subject to numerous landslides. The new geotech engineer okayed the new Antelope-Pardee alignment. Marian has data on the corrections but not GIS data. POWER will digitize the data based on new information from Marian and Edison. Marian believes there is a record of Edison's tower movement and boundary decisions on their website.

  POWER is attempting to clarify the northern boundary of the 1,000 ft.-wide corridor to determine whether the Edison line will need to be crossed once or twice to avoid an FS Plan Amendment for realignment. POWER will validate the 1,000 ft.-wide corridor to SCE's centerline (which is off-set by 80 ft. from the Northern boundary).

  - On the South-East side of the corridor, the Southern end of Antelope-Pardee dips straight down before the canyon. BRRPT is going directly in following the existing 69KV; not around movie sets like SCE, which is a 2 mile re-routing requirement. This is the only divergence from the Antelope-Pardee line.

- After the new pole data is delivered, the area will be re-surveyed to be South of the Antelope-Pardee line. BRRTP may end up being North or South of the Antelope-Pardee line, although the assumption is that BRRTP will be on the South side and the survey corridors will need to be adjusted to move to the South. Antelope-Pardee did not follow the Northern boundary map for the 1,000 ft.-wide corridor.

5. Biology Updates

Vanessa states that the bird surveys, which will be including the Green Valley re-route, are happening this week. Botany teams will be going out again next week, and amphibian surveys will occur next week. The Desert Tortoise and Mojave Ground Squirrel surveys will occur at the end of June or in early July.

Nadia has been attempting to give Vanessa more information on the SCE right-of-way. She advised to proceed with caution until a definitive confirmation to her inquiries arrives.

- Section 7 Fish & Wildlife
  Marian states that Dehla from Fish & Wildlife has contacted her. Dehla received Nadia's survey data for the California Red Legged Frog and the Arroyo Toad. Marian wonders what, since the informal consultation hasn't officially begun, is the protocol for discussing the project with Fish & Wildlife? Marian states that she discussed the project and gave Della Linn's contact information.

  Linn states that BLM has collected fees for the consultation process. There will be two Fish & Wildlife biologists for the site assessments: Ashley Blackford will be handling the desert assessment, while Della will be handling the Angeles forest amphibians, fish and condors.

  Marian requests that Vanessa call Della, and Marian will forward Della's contact information. Vanessa will confirm with Della the flow of information during this phase.

- Green Valley Re-Route
  Marian would like to discuss the Green Valley re-route and whether it is possible to push it closer to private lands. Mike stated that moving it closer to the existing alignment would move it to the top of the mountain, where it becomes a concern to private citizens. LADWP has tried to site the re-route per public comments, so the line would be behind the mountain and unseen by private properties and utilize existing roads. LADWP is not committed to the re-route, it has only responded to public comments. If FS is opposed to the re-route, it can be eliminated.

c) **Biology Resources** (Vanessa Gutierrez, POWER; Dave Kelly, POWER; Nathan Sill, USFS; Katie VinZant, USFS; Patti Krueger, USFS)

Gutierrez explained that there are surveys currently being conducted for Federal, State, USFS and BLM sensitive species, as well as the mapping of the RCAs and species composition, to place appropriate buffers in sensitive areas. RCAs outside the corridors are also being identified; there is concern for downstream indirect effects and sedimentation.

There is concern about the long-term maintenance plans for the access roads and a need for a detailed restoration plan. The detailed restoration plan needs to address seed collection, invasive species, and use of herbicides and weed free materials.

The Biology team also notes the possibility of the migration and population, through the construction process, of invasive plant species. There are and will be washdown stations to try to minimize the spread of invasive plants, but some proliferation is inevitable. Any pesticides that plan to be used to control invasive species must be included in the EIS/EIR. Coordination with noxious weed personnel from the County will also be necessary.

Other areas of concern:

- Flight pathways and the avian risks they present through migration corridors
- Trash and micro-trash generated through the construction process
- Effects of construction and maintenance noise on sensitive species and riparian avian species
- Sedimentation and water quality concerns
- Expanded OHV, hunting and plant collecting access through improvement and construction of roads, and the risks that access presents to sensitive species

APPENDIX E: DETAILED CONSTRUCTION, OPERATION, AND MAINTENANCE PROCESS

THIS PAGE INTENTIONALLY LEFT BLANK

BARREN RIDGE RENEWABLE TRANSMISSION PROJECT

Detailed Construction, Operations and Maintenance Process

POWER ENGINEERS

BRRTP CONSTRUCTION, OPERATION AND MAINTENANCE

1.0 230 KV DOUBLE-CIRCUIT TRANSMISSION LINE

1.1 CONSTRUCTION SEQUENCE

Construction of a transmission line involves the following general sequence of events: surveying the centerline; identifying and constructing access roads; clearing right-of-way and tower sites (including construction yards and batch plants); installing foundations; assembling and erecting the towers; clearing, pulling, tensioning, and splicing sites; installing ground wires and conductors; installing counterpoise; switching station tie in; and cleanup and site reclamation. Various phases of construction would occur at different locations throughout the construction process for the Barren Ridge Renewable Transmission Project (BRRTP). This would require several contractors operating at the same time and in different locations.

The following section describes the construction components necessary for the assembly and installation of the proposed double-circuit transmission line. The description of transmission line construction sequencing and estimates for construction sites would also be relevant for the additional transmission line construction activities associated with the installation of the Castaic-Haskell Canyon #4 circuit on existing structures, and the reconductoring of the Barren Ridge – Rinaldi (BR-RIN) transmission line between the Barren Ridge Switching Station and the Rinaldi Substation.

1.1.1 Surveying Activities

The Los Angeles Department of Water and Power (LADWP) must first obtain survey permits for the portion of the Project crossing federal lands managed by the U.S. Department of Agriculture, Forest Service (USFS) and the U.S. Department of the Interior, Bureau of Land Management (BLM), and rights-of-entry for private lands. This would include the issuance of a 50-year term Special Use Permit to LADWP by the USFS and a 30-year term (renewable) Right-of-Way Grant issued by the BLM. For survey on affected private lands, LADWP would need to negotiate rights-of-entry with the local landowners. Once survey permits are obtained, construction survey work would consist of locating the centerline, tower center hubs, ROW boundaries, and tower access roads, some of which would be located outside of the ROW boundaries. Whenever possible, location of the ROW and Project facilities would be laid out to avoid identified sensitive resources. All of these activities would begin approximately one year prior to the start of construction. Cultural resources and necessary additional threatened and endangered species intensive surveys would be conducted once the survey of the centerline and access roads is completed and clearly marked.

Necessary pre-construction geotechnical investigations would include geological field mapping of each tower site, and borings by drill rig for soil sampling and bedrock corings to determine soil densities and bedrock strength. Test locations would include angle points between the Barren Ridge Switching Station and the Angeles National Forest (ANF), and five to ten locations along the selected alignment within the ANF. Seismic analysis of tower sites for slope stability would also be necessary in mountainous areas of the ANF. Existing roads would be used as much as possible, but some new roads could be required.

1.1.2 Preconstruction Weed Removal

LADWP/ANF/BLM shall prepare and implement a comprehensive, adaptive Weed Control Plan on NFS/BLM lands for pre-construction and construction invasive weed abatement. A pre-construction weed inventory shall be conducted by surveying all areas subject to ground-disturbing activity, including, but not limited to, tower pad preparation and construction areas, tower removal sites, pulling and tensioning

sites, assembly yards, and areas subject to grading for new or improved access and spur roads. In areas subject to ground disturbance, weed infestations shall be treated prior to construction according to control methods and practices for invasive weed populations designed in consultation with the USFS/BLM. The Weed Control Plan shall be updated and utilized for eradication and monitoring post construction. Weed control treatments shall include all legally permitted herbicide, manual, and mechanical methods applied with the authorization of the USFS/BLM. The application of herbicides shall be in compliance with all state and federal laws and regulations under the prescription of a Pest Control Advisor (PCA), where concurrence has been provided by the USFS/BLM, and implemented by a Licensed Qualified Applicator. Herbicides shall not be applied during or within 24 hours of a scheduled rain event. Herbicides shall not be used within Riparian Conservation Areas (RCAs) on the ANF without approval of the USFS. In riparian areas, only water-safe herbicides shall be used. Herbicides shall not be applied when wind velocities exceed six miles per hour. Where manual and/or mechanical methods are used, disposal of the plant debris will follow the regulations set by the USFS/BLM. The timing of the weed control treatment shall be determined for each plant species in consultation with the USFS/BLM (on NFS/BLM lands, respectively) with the goal of controlling populations before they start producing seeds.

1.1.3 Construction of Access Roads

The construction, operation, and maintenance of the proposed transmission line would require that heavy vehicles access tower sites along the right-of-way. Where new access roads are required, they would be constructed to support the weight of these vehicles and would typically be 16 feet wide, consisting of a 14-foot driving surface with a side drainage system between one and two feet in width. Permanent roads would be constructed where necessary for operation or maintenance, or where it is required by the landowner or land managing agency. Road standards would be addressed specifically in the Construction, Operation, and Maintenance Plan (COM Plan) and the Plan of Development (POD) during the engineering phase of the Project, and prior to a Notice to Proceed from the USFS and BLM.

Dependent upon final design and mitigation, some temporary access roads may be constructed as part of the Project. These would typically be 16 foot wide roads, but would typically have no improved ditch drainage systems. Most temporary roads would be constructed by crushing vegetation. In some areas, material and topsoil from the temporary roads would be bladed to one or both sides to facilitate rehabilitation. Following construction, bladed material can be re-spread across the disturbed road section. Seeds and roots contained within the re-spread topsoil layer normally provide a natural source for new growth.

Existing paved and unpaved highways and roads would be used where possible. Roads along existing utility corridors would also be used where possible to minimize new access road construction. In locations where existing roads can be used that are located in close proximity to the proposed centerline of the transmission line, only spur roads to the tower sites would be required. New access roads and spur roads would likely be constructed into the right-of-way where existing roads do not exist. Table 1 lists the estimated ground disturbance of access and spur roads based on terrain.

TABLE 1. ACCESS AND SPUR ROAD GROUND DISTURBANCE ESTIMATES

Ground Disturbance Categories	Access Roads		Spur Roads (average width 16 feet)	
	Average Miles of Roads Per Mile of Transmission Line	Average Acres of Disturbance Per Mile of Transmission Line*	Average Miles of Roads Per Mile of Transmission Line	Average Acres of Disturbance Per Mile of Transmission Line
1. Existing roads or agricultural land; no widening anticipated	n/a	n/a	0.3	0.6
2. Existing 8 ft wide roads that require an additional 8 ft of widening	1.0 to 2.5	Permanent 0.9 to 2.4	0.3	0.6
3. Construct new road on flat terrain (0-10%)	1.0 to 2.5	Permanent 1.9 to 4.8	0.3	0.6
4. Construct new road on sloping terrain (10-20%)[1]	2.5 to 4.0	Temporary 7.3 to 11.6 Permanent 4.8 to 7.7	0.5	1.0
5. Construct new road on steep terrain (20-30%)[1, 2]	4.0 to 6.0	Temporary 23.3 to 34.9 Permanent 7.7 to 11.6	0.8	1.6
6. Construct road on very steep terrain (greater than 30%)[1, 2]	6.0 to 8.0	Temporary 69.8 to 93.1 Permanent 11.6 to 15.5	1.0	1.9

[1] After construction of the transmission line, all access roads in Categories 4 through 6 would be restored back to 16 feet wide.
[2] On steep terrain (approximately 25% or higher) with limited access on the Angeles National Forest, the USFS may require Helicopter Mitigation.

Wherever possible, roads would be built at right angles to streams and washes. Culverts or other drainage structures would be installed as necessary across drainages, but the roads would usually follow the natural grade. In addition, road construction would include dust-control and erosion control measures in sensitive areas. All existing roads would be left in a condition equal to or better than their condition prior to the construction of the transmission line without changing their service level. Gates would be installed where required at fenced property lines to restrict general vehicular access from or to the right-of-way. Where identified within the environmental studies for mitigation purposes, access roads may be excluded or limited within specific sensitive areas, such as Riparian Conservation Areas (RCAs) on the Angeles National Forest.

1.1.4 Clearing Right-of-Way

The clearing of some natural vegetation may be required. However, selective clearing would be performed only when necessary to provide for surveying, electrical safety clearances, line reliability, and maintenance. Trimming or removal of mature vegetation, under or near the conductors, would be done to provide adequate electrical clearance as required by the National Electrical Safety Code, the North American Electrical Reliability Corporation, and California Public Utilities Commission General Order 95 standards.

Trees that could fall onto the lines or affect lines during wind-induced line swing would be removed. Normal clearing procedures are to top or remove large trees and not disturb smaller trees. Where there is a direct conflict between trees and clearance standards, the removal of trees would be jointly reviewed and agreed upon between LADWP and the owners or managers of the property. Rights-of-way would not be chemically treated unless necessary to comply with requirements of a permitting agency. On National Forest System (NFS) lands, approved herbicides would be utilized within the Project area on select invasive plant species. Invasive plant surveys and control would continue for the life of the Project.

1.1.5 Tower Site Clearing

After access roads are developed, preparation of individual structure sites would be required to install the structures. At tower locations, work areas of up to 200 feet squared in flat terrain and up to 200 by 250 feet in areas with slopes greater than eight percent may be needed. Within the work areas, at some tower locations, a level cleared area (pad) may be necessary to complete the construction of the towers. However, many tower sites would be considerably smaller depending on the size of the tower, the terrain, resource considerations, and whether helicopter construction was used, among other factors. The work area would be required for the location of tower footings, assembly of the tower, and the necessary crane maneuvers. Vegetation would be mostly crushed, and cleared only when necessary. All pads not needed for normal transmission line maintenance would be graded to blend as near as possible with the natural contours, and revegetated where required by a permitting agency. See Table 2 for tower specifications and Table 5 for estimated temporary and permanent ground disturbance associated with the double-circuit steel lattice towers.

TABLE 2. DOUBLE-CIRCUIT STEEL LATTICE TOWER SPECIFICATIONS

Tower Placement Details	Specifications	
	Categories 1 through 3 Flat (0 – 10% slope)	Categories 4 through 6 Mountainous (10 – 30% slope)
Towers per mile	±5	±5
Average span length	1,100 ft.	1,000 ft.
Average height Ground to lowest attachment	115 ft.	105 ft.
Upper body height	52 ft.	52 ft.
Overall tower height	167 ft.	157 ft.
Typical range of heights of new towers	120 – 195 ft.	110 – 185 ft.

1.1.6 Staging Areas and Batch Plants

It is anticipated that one or two construction yards or staging areas would be required for materials storage, construction equipment, construction vehicles, and temporary construction offices. Staging areas would be approximately five acres in size, and located centrally or near each end of the transmission line route. The staging areas would be located on previously disturbed private land and would be level and surfaced with crushed aggregate base. The LADWP would negotiate with landowners for specific locations of the staging areas.

Concrete for use in constructing foundations would be dispensed from a portable concrete batch plant located at approximately 15 mile intervals. A rubber-tired flatbed truck and tractor would be used to relocate each plant along the right-of-way. Commercial ready-mix concrete would be used when access to tower construction sites is economically feasible.

The construction yards and batch plants would be located on private land and serve as field offices, reporting locations for workers, parking space for vehicles and equipment, sites for material storage, and stations for equipment maintenance. Facilities would be fenced and their gates locked. Security guards would be stationed where needed. See Table 3 for estimated ground disturbance associated with the staging sites and batch plants.

TABLE 3. STAGING SITES AND BATCH PLANT GROUND DISTURBANCE ESTIMATES

Disturbance Description	**Categories 1 through 3 Flat (0 – 10% slope)***	
	Maximum Estimated Disturbance Dimension per site	**Average Disturbance**
Material staging sites (2 sites)	400 x 540 ft. (5 acres)	N/A
Concrete batch plants (3 sites maximum)	2 acres, 30 mile haul distance	0.2 acre per mile
Total Average Disturbance	**0.2 acre per mile**	

*Material staging sites and concrete batch plants would not be built on terrain above 10% slope.

1.1.7 Foundation Installation

Tower foundations for the lattice structures would consist of drilled concrete piers. The foundation process would start with the boring of four holes for each lattice structure or one hole for each TSP. The holes would be bored using truck- or track-mounted excavators with various diameter augers to match diameter and depth requirements of the foundation sizes.

For a typical suspension lattice tower, each hole would typically be four feet in diameter and 25 feet deep, depending on soil conditions. For the larger angle or dead-end structures, foundations could be up to 30 or more feet deep, depending on soil conditions. Each foundation would extend above the ground line between six inches and four feet. In extremely sandy areas, soil stabilization by water or a gelling agent may be used prior to excavation. Refer to Figure 1 and Figure 2 for typical foundation details for double-circuit towers.

Following excavation of the foundation holes, each footing would be constructed by placing formwork, reinforcing steel and a tower stub into the foundation hole, positioning the stub, and encasing it in concrete. Reinforcing steel cages would be assembled at laydown yards and delivered to each structure location by flatbed truck. Spoil material would be spread around the tower site and used for fill where suitable. The foundation excavation and installation would require access to the site by a power auger or drill, a crane, material trucks, and ready-mix trucks. Typical suspension structures would require approximately 25 to 40 cubic yards of concrete and dead-end structures would require approximately 120 cubic yards of concrete.

1.1.8 Tower Assembly and Installation

The size of the work areas for structures (assembly and installation sites) would be approximately 40,000 to 50,000 square feet (1 acre = 43,560 ft^2) depending on terrain. The location of these sites has not yet been determined, but exact locations would be identified within the COM Plan and POD prior to a Notice to Proceed from the agencies. Lattice towers would be assembled at each site, installed and bolted to the foundations. Bundles of steel members and associated parts would be transported to each tower site by truck. Steel members would be assembled into subsections of convenient size and weight on the ground. Assembly would be facilitated with a small rough-terrain crane. The assembled subsections would be erected into place by a large crane and then fastened together in the air to form a complete tower. See Figure 3 for an illustration of typical tower assembly and installation activities.

FIGURE 3. TYPICAL TOWER ASSEMBLY AND INSTALLATION ACTIVITIES

FOUNDATION INSTALLATION
BLADE WHERE NECESSARY
DISCLAIMER: FIGURE NOT TO SCALE

1.1.9 Conductor Installation

After the towers are erected, insulators, hardware, and stringing sheaves would be delivered to each tower site. The towers would be rigged with insulator strings and stringing sheaves at each ground wire and conductor position. Sheaves are rollers, temporarily attached to the lower end of the insulators that allow the conductor to be pulled, or "strung," along the line.

For public protection during wire installation, temporary guard structures would be built next to highways, railroads, power lines, structures, and other major obstacles. Guard structures would consist of

H-frame poles placed on either side of an obstacle. These structures would prevent ground wire, conductor, or equipment from falling on an obstacle. Equipment for installing guard structures would include augers, line trucks, pole trailers, and cranes. A guard structure would be anticipated to be necessary every five miles. The amount of ground disturbance would typically be 200 feet by 300 feet. The guard structures would be left in place until conductors and ground wires were strung, tensioned and clipped; this time frame would be approximately three weeks or longer depending on conditions. Guard structures may not be necessary for small roads. In such cases, other safety measures, such as barriers, flagmen, or other traffic control, would be used.

Pilot lines would be pulled (strung) from tower to tower by a helicopter and threaded through the stringing sheaves at each tower. The pilot line can be used to pull in the ground wire, but is used to pull in a larger-diameter, stronger pulling line for the conductor. The larger-diameter, stronger line—pulling line—would be attached to the conductors to pull them onto towers. This process would be repeated until the ground wire or conductor is pulled through all sheaves. Bundled conductors would be pulled together with the assistance of a running board. The running board attaches the bundled conductor to the pulling line.

Ground wire and conductors would be strung using powered pulling equipment at one end and powered braking or tensioning equipment at the other end of a conductor segment as shown on Figure 4. Sites for tensioning equipment and pulling equipment would be approximately 2.5 miles apart.

THREE DRUM PULLER
CLEAN-UP & REHABILITATION
TENSIONER
REELS OF CONDUCTOR
DISCLAIMER: FIGURE NOT TO SCALE

To the greatest extent practical, pulling and tensioning sites would be located within the transmission ROW. However, some pulling and tensioning sites may occur outside the ROW. The tensioning and pulling sites could be as large as 200 feet by 500 feet, however they would be limited in size depending on each specific location and what is reasonable for safe construction practices. The size of each site would be limited as much as possible and would be designed in coordination with the responsible property owner or land management agency. Depending on topography, some grading may be required at pulling and tensioning sites to create level pads for equipment. Tensioners, line trucks, wire trailers, and tractors needed for stringing and anchoring the ground wire or conductor would be located at the tensioning sites. A puller, line trucks, sag cat and tractors would be needed for pulling and temporarily anchoring the ground wire and conductor. Table 5 includes ground disturbance estimates for conductor installation (helicopter fly yards, portable helicopter landing pads, pulling and stringing sites, and sleeving and stringing operations).

After installing the conductor ground wire or fiber optic shield wire, sagging, clipping and dead-ending activities, terminating the conductors at dead-end structures, would be performed. This process would involve adjusting the position of the conductors and shield wires, removing stringing sheaves, and permanently attaching the conductor to the insulators with specialized hardware.

1.1.10 Counterpoise Installation and Grounding Practices

Part of standard construction practice prior to wire installation would involve measuring the resistance of tower footings and installation of counterpoise (grounds) as needed. To determine if a tower would require counterpoise, ground resistance measurements would be taken at towers sites after the installation of the foundations and structures. The measurements would be evaluated to determine the numbers and locations of structures requiring counterpoise. If the resistance to remote earth for each transmission tower is greater than 10 ohms, counterpoise (grounds) would be installed to lower the resistance to 10 ohms or less. Counterpoise would consist of a bare copper-clad or galvanized steel cable buried a minimum of 12 inches deep, extending horizontally from one or more tower legs for approximately 200 feet. Typical counterpoise installation would include two installations per structure on opposite tower legs. Four installations per tower could be required in certain circumstances.

In addition to counterpoise installation, standard grounding practices during construction would include both temporary and permanent grounding of equipment and structures, such as fences or pipelines, as necessary to reduce any potential magnetically induced voltages to harmless levels. Such practices could include electrical isolation of equipment or structures and the installation of grounding wires.

1.1.11 Switching Station Tie-in

At the proposed Haskell Canyon Switching Station, the transmission lines would be connected into and out of the switching station through dedicated station structures within the switching station, commonly referred to as "bus."

1.2 UPKEEP OF CONSTRUCTION SITES

Construction sites, material storage yards, and access roads would be kept in an orderly condition throughout the construction period. Refuse and trash would be removed from the sites and disposed of in an approved manner. Oils and fuels would not be dumped along the line. Oils or chemicals would be hauled to a disposal facility authorized to accept such materials. No open burning of construction trash would occur without agency approval.

Microtrash would be cleaned daily from all work areas within known California condor habitat. Microtrash is a term used to describe small bits of debris like bottle caps, rags, screws, bolts, wires, glass, and other materials found in condor habitat.

1.3 HAZARDOUS MATERIALS WITHIN THE PROJECT AREA

Petroleum products such as gasoline, diesel fuel, helicopter fuel, crankcase oil, lubricants, and cleaning solvents would be present within the Project area during construction. These products would be used to fuel, lubricate, and clean vehicles and equipment. These products would be containerized by fuel trucks or by approved containers. When not in use, hazardous materials would be properly stored to prevent drainage or accidents.

Hazardous materials would not be drained onto the ground or into streams or drainage areas. Totally enclosed containment shall be provided for all trash. All construction waste including trash and litter, garbage, other solid waste, petroleum products, and other potentially hazardous materials would be removed to a disposal facility authorized to accept such materials.

All construction, operation, and maintenance activities would comply with all applicable federal, state, and local laws and regulations regarding the use of hazardous substances.

The construction or maintenance crew foreman would insure that all applicable laws are obeyed. In addition, an on-site inspector would be present during construction to make sure that all hazardous materials are used and stored properly. A health and safety plan would be developed as part of the COM Plan and POD during the engineering and preconstruction phase of the Project.

1.4 SITE RECLAMATION

The ROW, including temporary construction sites, and any temporary ground disturbance outside of the ROW that may have been caused during or due to the construction of the Project (e.g., temporary access roads, staging sites, assembly yards) would be restored as required by the property owner or land management agency. All practical means would be used to restore the land to its original contour and to restore natural drainage patterns along the ROW. Because revegetation would be difficult in many areas of the Project where precipitation is minimal, it would be important to minimize disturbance during construction. All practical means would be used to increase the chances of vegetation reestablishment in disturbed areas.

The total construction period would be approximately two years. The COM Plan that would be completed during the engineering and preconstruction phase of the Project would address specific site reclamation of all disturbed areas.

1.5 FIRE PROTECTION

A Fire Management Plan would be developed for the Project and all applicable fire laws and regulations would be observed during the construction period. All personnel would be advised of their responsibilities under the applicable fire laws and regulations, including taking practical measures to report and suppress fires.

1.6 CONSTRUCTION MONITORING

An approved compliance program would be developed to address mitigation requirements associated with the avoidance of sensitive plant and animal species, cultural sites, or other sensitive features located

within or adjacent to the Project. Prior to construction, these measures will be described in detail and included in the POD.

1.7 THREE-CIRCUIT TOWER MITIGATION

A temporary transmission line would be constructed to keep the BR-RIN circuit energized during construction of the three-circuit towers. After the temporary line is constructed, the existing BR-RIN single-circuit towers would be removed to allow the new three-circuit towers to be constructed within the existing ROW. Once construction of the three-circuit towers is completed, the temporary transmission line would be removed.

The temporary transmission line would be 7.5 miles long and would consist of wood and steel single poles with an average height of 95 feet, a 3-foot by 3-foot footprint, and an average of eight poles per mile. Construction would occur within a temporary 80- to 100-foot ROW. Refer to Table 4 for specifications and to Table 5 for ground disturbance estimates. The majority of the temporary transmission line would be constructed along San Francisquito Road. Portions would also be constructed along Elizabeth Lake Road and Johnson Road. Pole placement would be adjacent to public roadways wherever possible. If necessary, temporary ROW on private property would be needed where poles could not be placed within public road ROW. The majority of poles would be direct-embedded when set in place and would not require a permanent foundation. Where additional strength is necessary at larger angle points, steel poles would be required, which could require an excavation approximately 6 feet in diameter by 20 feet deep to accommodate the concrete pier foundation that would be cast in place. Once all the poles have been constructed and the conductor installed, the existing BR-RIN circuit would be connected into the temporary line and energized. The construction would require establishment of a staging area, work areas around poles, and pull and tension sites. Access to pole sites and pull and tension sites would be from the adjacent roadways.

Approximately seven miles of the existing BR-RIN single-circuit towers would be removed, with existing ROW utilized to access the existing towers. The new three-circuit towers would be placed within the existing ROW, utilizing existing access roads. Helicopter Mitigation, as described in this section below, would be applied in steeper terrain crossing the Angeles National Forest if additional access is required. If additional access roads, considered to be longer than 300 feet, are necessary, specific locations and construction method (either helicopter or conventional) would be coordinated with the USFS. The new three-circuit tower would require a 25-foot by 30-foot structure footprint and an average of seven structures per mile; the average structure height would be 170 feet, with a maximum tower-to-tower span length of 780 feet. Structures would be installed in the same locations as the existing BR-RIN structures within the limits of standard tower design. The construction process for the new three-circuit towers would be the same as the double-circuit towers discussed above. After completion of construction of the three-circuit towers, the temporary transmission line would be removed and all temporary staging and work area land disturbances would be restored as close to previous conditions as possible and revegetated as required. Restoration practices would be consistent with Section 1.11 Decommissioning of Transmission Lines.

TABLE 4. THREE-CIRCUIT TOWER SPECIFICATIONS

Tower Placement Details	Specifications	
	Triple-Circuit	Temporary Transmission Line
ROW acquisition	None (within existing)	80-100 ft
Structures per Mile	7	8
Average span length	750 ft	650 ft

Tower Placement Details	Specifications	
	Triple-Circuit	Temporary Transmission Line
Average height (ft) Ground to lowest attachment	120	60
Upper body height	50	45
Overall tower height	170	105
Typical range of heights of new towers	150 - 180 ft.	95 - 105 ft.

1.8 HELICOPTER MITIGATION

The following sites and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas and associated temporary access roads, tower structure vegetation clearing, guard structures at major crossings, and access road pullouts. Refer to Table 5 for ground disturbance estimates for the Helicopter Mitigation.

The transmission line materials (tower steel, conductor reels, structure hardware, etc.) would be delivered by truck to the helicopter fly yards/staging areas. Vegetation clearing may be required at these sites to ensure safe working conditions. The fly yards/staging areas would serve as helicopter support yards for fueling and maintenance, as well as for the transport of materials and personnel. Towers may also be assembled in sections at these yards prior to delivery to the tower sites. Heavy lift helicopters would then fly the towers from the yards to the tower sites.

Portable landing pads would be located at each tower site. These pads would allow helicopters to load and unload personnel, tools, and equipment necessary for construction of foundations and assembly of tower structures. Helicopter-constructed towers that would not be in close proximity to existing access roads would utilize micropile foundations. For each tower leg, micropile foundations would use a group of three to eight 6- to 9-inch diameter casings that would be drilled and grouted into the ground. The exposed portion of the pile group would be encased in a reinforced concrete cap from the top of the casings to a depth anywhere from one to eight feet below the ground surface, depending on the terrain. Figure 5 illustrates the plan view and sections of a micropile foundation.

SUPPORT

Conductor installation would proceed as for double-circuit tower installation. The equipment necessary for conductor installation would be large, heavy construction equipment that could only be brought in by truck. Some NFS roads could need maintenance or improvement to allow pulling and tensioning, but no new access or spur roads would be created for conductor installation on the helicopter-constructed towers.

PRELIMINARY IMPROVED ACCESS ROAD SUMMARY:

ROAD LENGTH	5,800 FT
ROAD WIDTH	
EXISTING	14 FT
PROPOSED	22 FT
MAXIMUM SLOPE	15 %
MINIMUM CENTERLINE RADIUS OF CURVES	80 FT

NOTES:

THE ALIGNMENT OF THE PROPOSED PAVED ACCESS ROAD FOLLOWS THAT OF THE EXISTING PATROL ROAD.

THE EXISTING ACCESS ROAD WILL NEED TO BE WIDENED AND PAVED TO ALLOW SERVICE VEHICLES ACCESS TO THE PROPOSED STATION. WIDENING THE ROAD WILL REQUIRE ADDITIONAL GRADING AND EARTHWORK.

THE PROPOSED ACCESS ROAD MAY BE SUBJECT TO THE APPROVAL THE LOS ANGELES COUNTY FIRE DEPARTMENT.

THE EARTHWORK QUANTITIES AND CONSTRUCTION COST ESTIMATES LISTED ON SHEET 1 DOES NOT INCLUDE THE CONSTRUCTION OF THE IMPROVED ACCESS ROAD.

IN THIS ALTERNATIVE, THE PROPOSED STATION EXTENDS INTO PRIVATE PROPERTY, RIGHTS TO THIS PRIVATE PROPERTY MUST BE ACQUIRED BY LADWP.

PLEASE NOTE THAT THIS DESIGN IS PRELIMINARY. THE TOPOGRAPHY, PROPRETY LINES, PROJECT LIMITS AND DESIGN VARIABLES ARE APPROXIMATE AND THUS SUBJECT TO CHANGE. A NUMBER OF REMAINING ENGINEERING AND ENVIRONMENTAL ISSUES MUST STILL BE RESOLVED. THIS EXHIBIT, AND CORRESPONDING CONSTRUCTION COST ESTIMATE, ARE FOR PRELIMINARY SITE EVALUATION PURPOSES ONLY.

PRELIMINARY GRADING - ALTERNATIVE (A-4) - 600' x 500' PAD
OPTIMAL TRANSMISSION ENGINEERING STATION ALIGNMENT
HASKELL CANYON SWITCHING STATION

5.0 EXPANSION OF BARREN RIDGE SWITCHING STATION

LADWP proposes expansion of the existing Barren Ridge Switching Station to the east side by 235 feet by 500 feet, for a total station size of 485 feet by 500 feet (approximately 5.6 acres). The expansion area of the station would include electrical structures and equipment for the addition of transmission lines, a material staging area, roadway within the station, and drainage area. Figure 8 illustrates the preliminary design layout for the station.

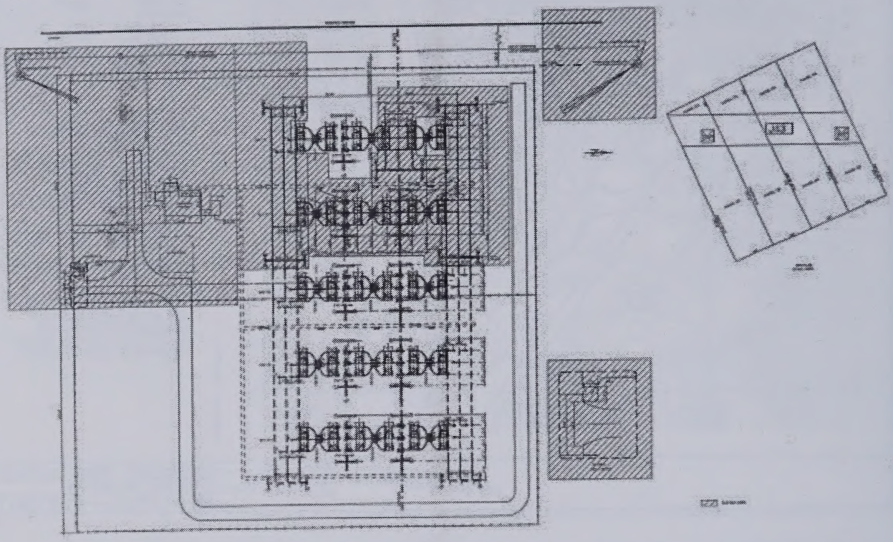
Expansion of the existing switching station would be very similar to the construction of the Haskell Canyon Switching Station as described above. Expansion would consist of preconstruction surveys, site preparation and grading, installation of reinforced concrete foundations, installation of electrical conduits for equipment power and control, and installation of structures and equipment.

Necessary pre-construction geotechnical on-site investigation would include two test pits excavated by a backhoe to investigate soil density and settlement, and four cone penetration test locations on-site to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

It is estimated that 700 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 80 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 90-day working period. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks and flatbed trailers. Cranes, man-lifts, portable welding units, line

trucks, and mechanic trucks would also be required. An estimated 8 months with approximately 60 workers would be required to expand the station.

FIGURE 8. BARREN RIDGE SWITCHING STATION EXPANSION LAYOUT



1.9 OPERATION OF TRANSMISSION LINES

The nominal voltage for the BRRTP transmission line would be 230 kV AC. There may be minor variations of up to five percent above the nominal level depending upon load flow.

1.9.1 Permitted Uses

After the transmission line has been energized, land uses that are compatible with safety regulations (such as agriculture and grazing) would be permitted in and adjacent to the right-of-way. Incompatible land uses within the right-of-way include construction and maintenance of inhabited dwellings, and any use requiring changes in surface elevation that would affect electrical clearances of existing or planned facilities.

Land uses on public lands that comply with local regulations would be permitted adjacent to or within the ROW, with require approval from the appropriate agency. Permission to use the ROW on private lands would have to be obtained from the utility owning the transmission line.

1.9.2 Safety

Safety is a primary concern in the design of this 230 kV transmission line. The AC transmission line would be protected with power circuit breakers and related line relay protection equipment. If conductor failure occurs, power would be automatically removed from the line. Lightning protection would be provided by overhead ground wires along the line. Electrical equipment and fencing at the switching station would be grounded. All fences, metal gates, pipelines, and other metal components that cross or are within the transmission line ROW would be grounded to prevent electrical shock. If applicable, grounding outside of the ROW may also occur.

1.10 MAINTENANCE OF TRANSMISSION LINES

The 230 kV transmission line would be inspected several times annually by both ground and air patrols. Maintenance would be performed as needed. When access is required for non-emergency maintenance and repairs, LADWP would adhere to the same precautions and procedures that were taken during the original construction.

Emergency maintenance would involve prompt movement of repair crews to repair or replace any damaged equipment or infrastructure. Crews would be instructed to protect crops, plants, wildlife, and other resources of significance. Restoration procedures following completion of repair work would be those prescribed for project implementation construction. The comfort and safety of local residents would be provided for by limiting noise, dust, and the danger caused by maintenance vehicle traffic. Details would be provided in the COM Plan and POD prior to line construction.

1.10.1 Vegetation Management

Vegetation management along the transmission line ROW would be required by the North American Reliability Council (NERC). In compliance with the NERC's Standard FAC-003-l, LADWP would prepare a Vegetation Management Plan for the BRRTP. The Vegetation Management Plan would be included in the COM Plan to be completed prior to the issuance of a Notice to Proceed from the USFS and BLM. Vegetation management would consist of routine tree trimming to maintain the required minimum 10-foot clearance from conductors to vegetation (California Public Resources Code [PRC] 4293); clearance of flammable brush vegetation within a 10-foot radius around the base of transmission line towers in accordance with California PRC 4292; and clearance immediately adjacent to access roads to permit adequate access to the facilities.

1.10.2 Access Road Maintenance

Ongoing access road maintenance would be conducted in accordance with existing or new road authorizations issued to LADWP. Access road maintenance consists of those activities necessary to allow continued access to the ROW and/or each tower structure. These activities may include grading, and maintenance of drainage systems, bridges, culverts, fences, gates and signs. Motor graders, backhoes, dump trucks and pickups are used to maintain access roads.

1.11 DECOMMISSIONING OF TRANSMISSION LINES

At the end of the useful life of the proposed Project, if the facility were no longer required, or if extension of the authorizations were not granted by federal land agencies at the time they expired, the transmission line would be abandoned. Subsequently, conductors, insulators and hardware would be dismantled and removed from the ROW. Tower structures would be removed and foundations broken off below ground surface.

If the line and associated ROW are abandoned at some future date, the ROW would be available for the same uses that existed prior to construction of the Project. Following abandonment and removal of the transmission line from the ROW, any areas disturbed to dismantle the line would be restored and rehabilitated as near as possible to their original condition.

2.0 ADDITION OF NEW 230 KV CIRCUIT

Between the proposed Haskell Canyon Switching Station and the existing Castaic Power Plant, LADWP proposes the addition of 12 miles of a new 230 kV transmission circuit onto existing Castaic – Olive 230 kV Transmission Line structures (towers 1-1 through 12-1). This new circuit would be called Castaic – Haskell Canyon #4 and would utilize the same conductor (2,156 kcmil "Bluebird" ACSS/AW) as that proposed for the new 230 kV transmission line between Barren Ridge and Haskell Canyon Switching Stations.

The addition of a new circuit on existing towers would require many of the same activities of a new transmission line (surveying of ROW, rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, and cleanup). However, all work would be within existing ROW and no new towers would be constructed. Some towers may need to be modified or reinforced to carry the additional weight of the new conductor. Specific towers requiring reinforcement would be determined following detailed design of the Project. Tower reinforcement would not alter the general design or the location of the structures. This process would generally include reinforced foundations or steel member replacements.

3.0 RECONDUCTORING

LADWP proposes the reconductoring of 76 miles of the existing BR-RIN 230 kV transmission line with larger conductors between the Barren Ridge Switching Station and Rinaldi Substation (towers 176-1 through 251-1). The existing conductors (954/ 2,312 kcmil) would be replaced with a new 1,433.6 kcmil "Merrimack" ACSS/TW/HS conductor. The new conductor would have a larger diameter that allows for greater electrical capacity.

The upgrade of the existing BR-RIN would also require many of the same activities of the new transmission line (surveying of ROW, rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, and cleanup). Removal of the existing conductor would be used to string a pulling line, and this line would then be used to pull in the new conductor. All work would remain within the existing 250-foot-wide ROW, with no additional ROW required. Some of the towers would need to be

modified, replaced, and/or have foundations reinforced or replaced to carry the additional weight of the new heavier conductor.

4.0 NEW HASKELL CANYON SWITCHING STATION

As a component of the BRRTP, LADWP proposes the construction of a new switching station in Haskell Canyon, south of the Angeles National Forest on LADWP-owned property at the convergence of several existing and proposed 230 kV transmission lines (the existing BR-RIN, the proposed double-circuit Barren Ridge-Haskell Canyon, existing Castaic-Northridge, Castaic-Sylmar, Castaic-Olive, and the proposed Castaic to Haskell Canyon).

The station would be approximately 500 feet by 600 feet to accommodate the necessary circuit positions, which are made up of equipment, such as steel support structures, circuit breakers, disconnect switches, and associated equipment, and a relay house and control house containing control and protective relaying equipment. The relay and control houses would each be approximately 30 feet long by 12 feet wide by 10 feet high and constructed of gray concrete block. The station yard would include a paved internal access road approximately 16 feet wide and would be enclosed by chain-link fencing with barbed-wire extension for security. Figure 6 illustrates the preliminary design layout for the station. Figure 7 illustrates the preliminary grading plan for the station.

Necessary pre-construction geotechnical investigation on-site would include six borings by a drill rig to investigate bedrock and soil stability and four cone penetration test locations after site grading to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

Construction of the new Haskell Canyon Switching Station would consist of preconstruction surveys, clearing and grading of access roads, site grading and drainage development, installation of concrete foundations and steel support structures, installation of below- and above-ground electrical conduits for equipment power and control, installation of below- and above-grade grounding conductors, and installation of control and relay houses. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks, and flatbed trailers. Cranes, man-lifts, portable welding units, line trucks, and mechanic trucks would also be required. Construction would require an estimated 12 months with approximately 60 workers.

Site preparation work for the station would involve clearing and grading of access roads, clearing of the switchyard site, the cut and fill grading of the site, and placement and compaction of structural fill that would serve as a base for switching station facilities. The site would be graded to maintain current drainage patterns as much as possible. A 16-foot wide paved road and 100-foot by 100-foot gravel parking area would be required. The yard would be covered with crushed-rock aggregate. Native vegetation would be re-established where possible outside the switchyard fence.

Following site grading and development, reinforced concrete foundations would be installed to support the steel structures and electrical equipment and control facilities. It is estimated that 1,500 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 180 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 120-day working period. Subsequent to the foundation installation, trenches would be dug to facilitate placement of copper conductors for the station grounding mat.

Multiple transmission lines would be terminated into the switching station (i.e., the new and existing Barren Ridge – Haskell and Castaic – Haskell Canyon transmission lines) and would need support and

require the installation of galvanized steel structures. An existing 115 kV transmission line may need to be relocated around the proposed station. High-voltage bus work consisting of aluminum jumpers and tubing would be installed within the station.

1.0 INTRODUCTION

The City of Los Angeles Department of Water and Power (LADWP) is proposing the Barren Ridge Renewable Transmission Project (BRRTP or Project) to access clean, renewable resources in the Tehachapi Mountains and Mojave Desert areas, and to improve reliability and upgrade transmission capacity.

LADWP, the US Department of Agriculture, Forest Service (USFS or Forest Service) and the U.S Department of the Interior, Bureau of Land Management (BLM) are preparing a joint Environmental Impact Statement (EIS) / Environmental Impact Report (EIR) for the proposed BRRTP. LADWP is the California Environmental Quality Act (CEQA) Lead Agency, while the USFS and BLM are the federal Co-Lead Agencies under the National Environmental Policy Act (NEPA). An EIS/EIR is an informational disclosure document used to inform agency decision makers and the public of the potential significant environmental effects of a project, identify possible ways to eliminate or minimize the potential significant effects, and describe reasonable alternatives to the Proposed Action /Project.

The purpose of the preliminary geotechnical evaluation is to assess the alternative corridors (segments) and proposed switching station within the Project study area in regards to potential geologic and seismic hazards and potential geologic impacts associated with implementation of the Project. The preliminary geotechnical evaluation: 1) presents regulatory framework, 2) provides an overview of the technical methodology used in collecting baseline conditions and evaluating impacts, 3) examines the affected environment within the study corridors and vicinity, 4) describes the impacts with respect to potential geologic and seismic hazards and potential geologic impacts from construction and operation of the Project, 5) evaluates the level of potential impacts based upon NEPA/CEQA significance criteria, and 6) presents specific recommendations for mitigation to reduce or eliminate potential impacts.

1.1 STUDY PERSONNEL

Ninyo & Moore personnel who compiled background data, conducted geotechnical analysis, and prepared the preliminary geotechnical evaluation included Michael Rogers, an Engineering Geologist with over 20 years of professional experience; Carol Price, an Engineering Geologist with over 25 years of professional experience; and Jalal Vakili, Ph.D., a Geotechnical Engineer with over 40 years of professional experience. Mr. Rogers and Ms. Price hold licenses with the State of California as Professional Geologists and Certified Engineering Geologists, and Dr. Vakili holds a license with the state as a Registered Civil Engineer. Jesse Lahman provided GIS support for the Project.

1.2 PROJECT DESCRIPTION

The BRRTP would be located in Kern and Los Angeles counties. As proposed by LADWP, it would be approximately 76 miles in length extending from the Barren Ridge Switching Station to Rinaldi Substation, and extending approximately 12 miles from the Castaic Power Plant to the proposed Haskell Canyon Switching Station. As shown in Figure 1-1, the proposed BRRTP would include the following:

1) Construction of approximately 61 miles of a new 230 kilovolt (kV) double-circuit transmission line from the LADWP Barren Ridge Switching Station to Haskell Canyon;
2) Addition of approximately 12 miles of a new 230 kV circuit on the existing double-circuit structures from Haskell Canyon to the Castaic Power Plant;
3) Reconductoring of approximately 76 miles of the existing Barren Ridge-Rinaldi (BR-RIN) 230 kV transmission line with larger capacity conductors between the Barren Ridge Switching Station and the Rinaldi Substation;
4) Construction of a new switching station in Haskell Canyon;
5) Expansion of the existing Barren Ridge Switching Station.

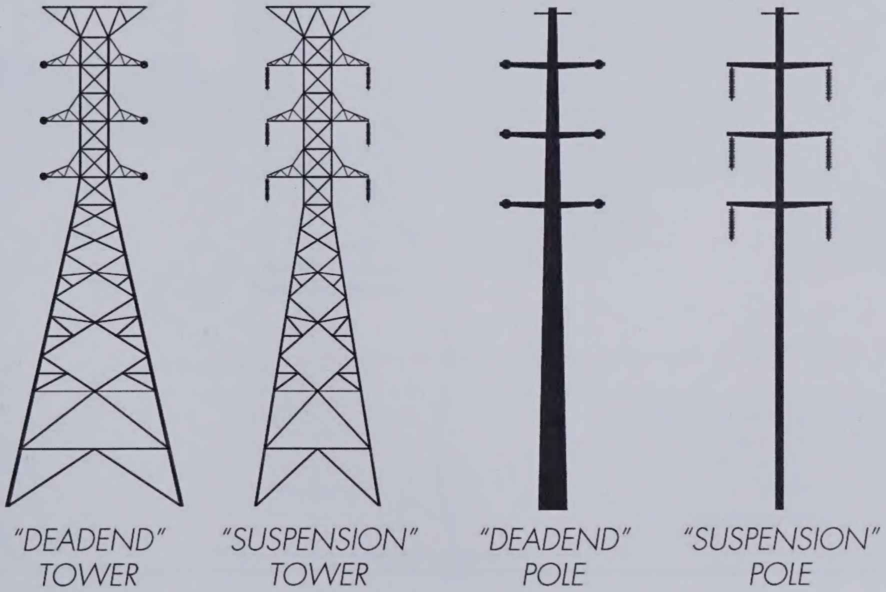
1.2.1. Construction of New 230 kV Double-Circuit Transmission Line

The proposed double-circuit 230 kV transmission line component of the BRRTP would consist of two alternating current (AC) circuits from the Barren Ridge Switching Station to the proposed Haskell Canyon Switching Station in Haskell Canyon.

The proposed structures for the new transmission line would primarily be self-supporting double-circuit steel lattice towers fabricated from galvanized steel members, as shown on the left side of Figure 1-2. Depending on the environmental conditions of the surrounding terrain, the height of the proposed lattice structures would range from 110 to 195 feet, with an average tower-to-tower span of 1,000 to 1,100 feet. Appendix C lists the structure specifications for the number of structures per mile, average span length, and average heights for towers and components. Exact structure placement would be determined during engineering surveys and detailed design studies for the selected Alternative route following the Record of Decision (ROD) on the EIS/EIR. A variety of engineering, constructability, existing access, and environmental issues would be considered during detailed structure siting within the permitted ROW.

"Dead-end" towers of self-supporting, steel-lattice design would be required periodically to add longitudinal strength along the line. Dead-end towers would also be used at turn (angle) locations along the line, at heavily loaded tower locations, and at specific utility crossings (e.g., other transmission lines) for added safety. Dead-ended towers are of the same basic configuration as suspension towers (non-angle structures), the difference being in the tower "arms," insulator systems, and tower weights.

FIGURE 1-2. TYPES OF TOWERS



Self-supporting, tubular steel poles (TSP) have been proposed by LADWP as an available mitigation structure where appropriate to reduce potential impacts, such as conflicts with cultivation on agricultural lands. The TSPs can reduce impacts in some cases due to a smaller footprint than the proposed self-supporting steel lattice structures; however, more TSPs per mile are necessary due to a shorter average span between structures. The TSPs would have an average height range between 95 and 180 feet, depending on the conditions of the surrounding terrain, with an average tower-to-tower span of 700 to 800 feet. Refer to Figure 1-2 for an illustration of the double-circuit poles.

For the majority of the alignment, the two new 230 kV circuits would be placed on new double-circuit transmission towers, but for approximately 1.5 miles, the circuits would be placed on existing four-circuit structures that are located just north of the proposed Haskell Canyon Switching Station. Between where the existing BR-RIN crosses Dry Canyon to the intersection of the Castaic transmission lines, LADWP has existing four-circuit towers with three vacant positions. The existing towers would be utilized in this section for the proposed 230 kV double circuit transmission line instead of constructing new towers. See Figure 1-3 for the location and illustration of the existing four-circuit towers to be utilized.

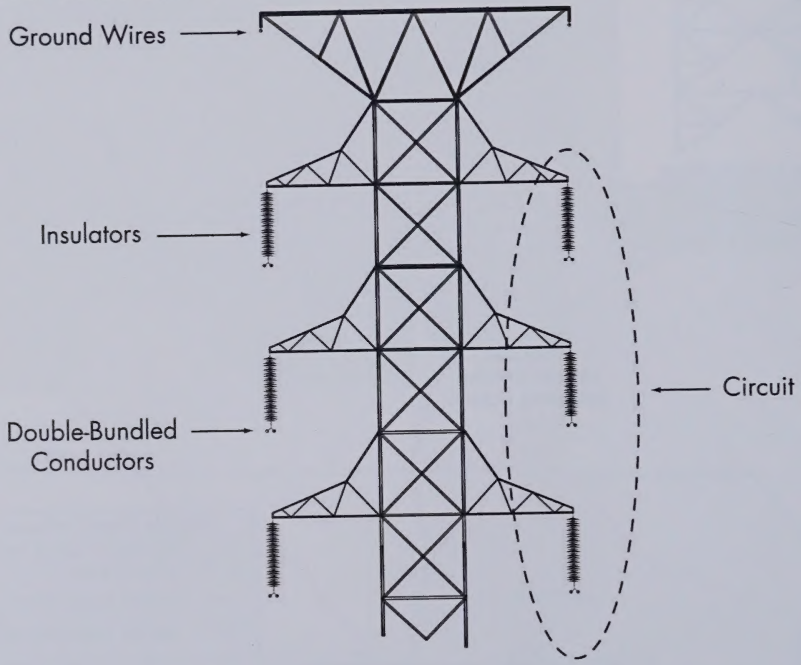
The self-supporting steel lattice structures and TSPs would utilize concrete foundations. Steel lattice structures would require four footings (one for each leg); TSPs would require single footings. Footings would be steel-reinforced concrete pier type and be cast in place. The typical design for the concrete footings for lattice structures would be between 2.5 and 5.0 feet in diameter, with an average depth of 20 feet depending on soil conditions. Typical design for single foundations for TSPs would include augured holes approximately five to seven feet in diameter and 15 to 30 feet deep, depending on conditions. Formwork steel reinforcing would be assembled in the hole prior to casting concrete in place. Reinforcing steel would become integral to the lower leg of the steel lattice structure during assembly. An above-ground concrete form placed over each hole would result in a final concrete foundation height of 0.5 to 2.0 feet above ground level.

As illustrated in Figure 1-4, Typical Tower Components, each tower carries conductors ("wires"), insulators, and ground wires. The conductor being considered for the new double-circuit 230 kV transmission line and installation of the Castaic – Haskell Canyon #4 circuit on existing structures is a bundled 715.5 kcmil "Starling" ACSS/AW. The reconductoring of the BR-RIN transmission line between Barren Ridge Switching Station and Rinaldi Substation would require a bundled 1,433.6 kcmil "Merrimack" ACSS/TW/HS conductor.

FIGURE 1-4. TYPICAL TOWER COMPONENTS



Each circuit would consist of three phases ("wires") as illustrated in Figure 1-4. To increase the current-carrying capability of the transmission lines and reduce power loss, the Proposed Action (Alternative 2) would utilize bundled conductors installed for each phase. The bundled conductors would consist of two conductor cables connected by a spacer. The new 230 kV double-circuit transmission line would consist of a total of six double-bundled (12 individual) wires.

Minimum conductor height above the ground, under normal operation of the line, is 30 feet. Greater clearances may be required in certain areas to allow for clearances over trees or other vegetation that

could pose a risk to the operation of the transmission line. Minimum conductor clearance would dictate the exact height of each tower based on topography and safety clearance requirements.

Insulators are used to provide the physical connection of conductors to structures. These system components are made of very low conducting materials (polymer insulators) that inhibit the flow of electric current from energized conductors to ground or to other energized system elements. Insulators and their associated hardware are to be configured in an "I" assembly to support conductors while maintaining required distances between phases and grounded structures. Each "I" string would consist of six-inch diameter insulators between six and eight feet long.

To shield conductors from hazard of direct lightning strikes by transferring lightning currents into the ground, overhead ground wires (shield wires) or fiber optic ground wire would be installed on top of new structures.

Construction of a transmission line involves the following general sequence of events: surveying activities; identifying and constructing access roads; clearing ROW and tower sites (including construction yards and batch plants); installing foundations; assembling and installing the towers; clearing, pulling, tensioning, and splicing; installing ground wires and conductors; installing counterpoise; switching station tie-in; and site upkeep and site reclamation. Various phases of construction would occur at different locations throughout the construction process for the BRRTP. This would require several contractors operating at the same time and in different locations. Refer to Appendix C for a description of each construction activity.

Existing paved and unpaved highways and roads would be used where possible. Roads along existing utility corridors would also be used where possible to minimize new access road construction. In locations where existing roads could be used, that are located in close proximity to the proposed or existing ROW centerlines, only new spur roads to the tower sites would be constructed. The specific locations and design of all new access and spur roads would be determined during final Project design.

It is anticipated that one or two construction yards or staging areas would be required for materials storage, construction equipment, construction vehicles, and temporary construction offices. Staging areas would be approximately five acres in size, and located centrally or near each end of the transmission line route. The staging areas would likely be located on previously disturbed land and would be level and surfaced with crushed aggregate base. The LADWP would negotiate with landowners for specific locations of the staging areas.

Routing

In 2007, a siting analysis was conducted to identify appropriate sites for a new 230 kV transmission line. Over 200 miles of routing opportunities were identified and referred to as Segments A through I (see Figure 1-5). These segments were then combined to create end-to-end routing "alternatives" as discussed in Section 8.2. All routing Segments were identified assuming the need for a 200-foot ROW for the new 230 kV transmission line and the use of conventional transmission line construction. However, as discussed in Section 8.2, the end-to-end alternatives have included specific mitigation measures to reduce certain impacts. These mitigation measures would eliminate the need for new ROW in some locations and would require the use of helicopters for tower assembly in designated areas on the ANF. Also, to the maximum extent possible, all existing access and spur roads would be utilized for the construction, operation, and maintenance of the BRRTP. Below is a brief description of each segment.

Segment A is 13 miles long and runs from LADWP's Barren Ridge Switching Station to the unincorporated community of Mojave, California. It would traverse four miles of BLM managed public lands and parallel LADWP's existing 230 kV Barren Ridge – Rinaldi Transmission Line (BR-RIN) and the 500 kV Pacific Direct Current Intertie (PDCI). It traverses four miles of BLM-managed lands.

Segment B is 27 miles long and starts just north of the unincorporated community of Mojave, California and travels south to a point one mile east of the Antelope Valley California Poppy Reserve. This segment parallels LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines for its entire length.

Segment C is 22 miles long and begins at the location as Segment B, north of the unincorporated community of Mojave, California. Segment C parallels the Los Angeles Aqueduct in a southwest direction to Cottonwood Creek. No existing transmission lines are located within the aqueduct corridor; however, Southern California Edison's (SCE's) Tehachapi Renewable Transmission Project's (TRTP) Alternative 10A is also proposed along the same corridor.

Segment D is 48 miles long and would traverse 16 miles of National Forest System (NFS) lands. This segment generally parallels the Los Angeles Aqueduct in a southwest direction, beginning near Cottonwood Creek and traveling to Lancaster Road. It then travels west to the Interstate 5 freeway utility corridor and continues southeast along LADWP's existing Castaic – Rinaldi corridor to the proposed Haskell Canyon Switching Station. Five high voltage transmission lines are located along the Interstate 5 section of the segment. Oil and gas pipelines are also located in the same I-5 corridor. Continuing further south near Castaic Power Plant, Segment D would be located to the south of two existing LADWP double-circuit 230 kV transmission line towers until reaching the proposed Haskell Canyon Switching Station.

Segment E is 11 miles long and begins near Cottonwood Creek at the intersection of Segments C and D. Segment E travels in a southeast direction and intersects Segment B one mile east of the Antelope Valley California Poppy Reserve. Three existing high voltage transmission lines (Midway-Vincent 500 kV, Antelope-Vincent 230 kV, and Antelope-Mesa 230 kV) are located within the corridor that Segment E would parallel. SCE's proposed TRTP Segment 4 is also proposed adjacent this same corridor.

Segment F is the shortest segment, at four miles in length, and begins at the intersection of Segments B and E one mile east of the Antelope Valley California Poppy Reserve. Three existing high voltage transmission lines (Midway-Vincent 500 kV, Antelope-Vincent 230 kV, and Antelope-Mesa 230 kV) are also located parallel to this segment.

The 115th Street Segment was proposed as a modification to avoid impacts to residents in the Antelope Valley near Segments F and H, described below. It begins mid-way within Segment F near SCE's Antelope Substation and parallels 115th Street south to the California Aqueduct. No existing transmission lines occur within this corridor; however, TRTP's proposed Segment 4 would be located along this alignment. This segment would split Segments F and H as shown in Figure 1-5 creating these Segments into F1, F2, H1 and H2.

Segment G is 21 miles long. Thirteen miles traverse National Forest System (NFS) lands. It travels south from the intersection of Segments B and F one mile east of the Antelope Valley California Poppy Reserve to the proposed Haskell Canyon Switching Station, located near the southern boundary of the ANF. It is a designated utility corridor containing LADWP's existing 230 kV BR-RIN and 500 kV PDCI lines. The BRRTP proposes to use its existing four-circuit structures for two miles, from towers 234-3 to 236-2 (see Figure 1-3).

Segment 2a is seven miles long. It would bypass the unincorporated community of Green Valley and follow an existing fire road through ANF. Segment 2a would not parallel existing transmission facilities, and a new utility corridor would be required.

Segment H is 20 miles long and would parallel SCE's Antelope-Pardee line. It starts near SCE's Antelope Substation at the intersection of Segments F and I and traverses 13 miles of NFS lands to the proposed Haskell Canyon Switching Station. As requested by the USFS, all portions of this segment that fall within the northern and southern borders of the ANF would be constructed entirely by the use of helicopters. The helicopter construction requirement was established by the USFS for consistency of transmission line construction within the existing Antelope-Pardee transmission line corridor. No new access roads would be constructed except those required for pulling and tensioning sites or staging locations for construction materials. The addition of the 115th Street Segment, described above, splits the Segment into H1 (northern portion) and H2 (southern portion).

Segment I is 32 miles long. It begins near the Antelope Substation at the intersection of Segments F and H, and heads southeast through the City of Palmdale, parallel SCE's existing high voltage transmission lines (Midway-Vincent 500 kV, Antelope-Vincent 230 kV, and Antelope-Mesa 230 kV). The segment continues directly south to an existing LADWP transmission line corridor, then continues in a southeast direction to the proposed Haskell Canyon Switching Station, parallel LADWP's existing high voltage transmission lines (Victorville-Rinaldi 500 kV and Adelanto-Rinaldi 230 kV). A majority of this segment would be located outside of NFS lands. Two miles would be located on NFS lands.

Segment J is located parallel to the southern portion of Segment D. Segment J would consist of a new single 230 kV circuit to be placed on existing double-circuit towers between Castaic Power Plant and the proposed Haskell Canyon Switching Station (see discussion in Section 1.2.2 below).

Three-Circuit Tower Mitigation

In areas where there are ROW expansion constraints and where LADWP has existing 230 kV transmission lines, LADWP is proposing to construct three-circuit towers within the existing ROW to carry the existing BR-RIN circuit and the two proposed Barren Ridge to Haskell Canyon (BR-HC) circuits. This would avoid various impacts, including the acquisition of residential property in the unincorporated communities of Willow Springs (milepost 27.1 to 27.6) and Elizabeth Lake and Green Valley (milepost 44.6 to 51.7). Refer to Figure 1-6 for an illustration of three-circuit tower types, and to Figure 1-7, the Three-Circuit Tower Mitigation Map, for proposed locations.

POWER ENGINEERS
LA DWP

LADWP must maintain the electrical service along the existing BR-RIN transmission line to avoid impacts to the hydroelectric power plants north of the Barren Ridge Switching Station. Therefore, a temporary transmission line would be constructed to keep the BR-RIN circuit energized during construction of the three-circuit towers. After the temporary line is constructed, the existing BR-RIN single-circuit towers would be removed to allow the new three-circuit towers to be constructed within the existing ROW. Once construction of the three-circuit towers is completed, the temporary transmission line would be removed. The temporary transmission line is expected to be in place from six to nine months.

The temporary transmission line would be 7.5 miles long and would consist of wood and steel single poles with an average height of 95 feet, a 3-foot by 3-foot footprint, and an average of eight poles per mile. Construction would occur within a new temporary 80- to 100-foot ROW. The majority of the temporary transmission line would be constructed along San Francisquito Road. Portions would also be constructed along Elizabeth Lake Road and Johnson Road. Pole placement would be adjacent to public roadways wherever possible. If necessary, temporary ROW on private property would be needed where poles could not be placed within public road ROW. The majority of poles would be direct-embedded when set in place and would not require a permanent foundation. Where additional strength is necessary at larger angle points, steel poles would be required, which could require an excavation approximately 6 feet in diameter by 20 feet deep to accommodate the concrete pier foundation that would be cast in place. Once all the poles have been constructed and the conductor installed, the existing BR-RIN circuit would be connected into the temporary line and energized. The construction would require establishment of a staging area, work areas around poles, and pull and tension sites. Access to pole sites and pull and tension sites would be from the adjacent roadways.

Approximately seven miles of the existing BR-RIN single-circuit towers would be removed, with existing ROW utilized to access the existing towers. The new three-circuit towers would be placed within the existing ROW, utilizing existing access roads. Helicopter Mitigation, as described in this section below, would be applied in steeper terrain if additional access is required. The new three-circuit tower would require a 25-foot by 30-foot structure footprint and an average of seven structures per mile; the average structure height would be 170 feet, with a maximum tower-to-tower span length of 780 feet. The construction process for the new three-circuit towers would be the same as the double-circuit towers discussed above. After completion of construction of the three-circuit towers, the temporary transmission line would be removed and all temporary staging and work area land disturbances would be restored as close to previous conditions as possible and revegetated as required.

Helicopter Mitigation

Within the ANF where the terrain is steep and access is limited, the USFS would require that the new double-circuit 230 kV structures be constructed with the use of helicopters (such as the Hughes 500 or Bell 212, or Sikorsky Skycrane). Although no specific locations for this mitigation have been identified for the Proposed Action, as defined, it is expected USFS would require the helicopter mitigation for construction in any area more than 300 feet from an existing road and with slopes greater than approximately 25 percent. The use of helicopters for the construction of transmission tower structures would eliminate the need for new access roads to structure locations, and would therefore minimize land disturbance associated with crane pads, structure laydown areas, and the trucks and tractors used for delivery of structures to sites. However, the following site and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas and associated access roads, tower structure vegetation clearing, guard structures at major crossings, and access road pullouts.

Temporary 24-foot wide access roads would be required to access the helicopter fly yards/staging areas. The transmission line materials (tower steel, conductor reels, structure hardware, etc.) would be delivered by truck to the helicopter fly yards/staging areas. Vegetation clearing may be required at these sites to

ensure safe working conditions. The fly yards/staging areas would serve as helicopter support yards for fueling and maintenance, as well as for the transport of materials and personnel. Towers may also be assembled in sections at these yards prior to delivery to the tower sites. Heavy lift helicopters would then fly the towers from the yards to the tower sites.

Portable landing pads would be located at each tower site. These pads would allow helicopters to load and unload personnel, tools, and equipment necessary for construction of foundations and assembly of tower structures. Helicopter-constructed towers that would not be in close proximity to existing access roads would utilize micropile foundations. For each tower leg, micropile foundations would use a group of three to eight 6- to 9-inch diameter casings that would be drilled and grouted into the ground. The exposed portion of the pile group would be encased in a reinforced concrete cap from the top of the casings to a depth anywhere from one to eight feet below the ground surface, depending on the terrain.

Conductor installation would proceed in the same manner as the double-circuit tower installation. The equipment necessary for conductor installation would be large, heavy construction equipment that could only be brought in by truck. Some NFS roads could need maintenance or improvement to allow pulling and tensioning, but no new access or spur roads would be created for conductor installation on the helicopter-constructed towers. After project completion, any maintained access roads to helicopter fly yards/staging areas to would be reduced to 16 feet.

1.2.2. Addition of New 230 kV Circuit

Between the proposed Haskell Canyon Switching Station and the existing Castaic Power Plant, LADWP proposes the addition of 12 miles of a new 230 kV transmission circuit onto existing Castaic – Olive 230 kV Transmission Line structures. The circuit would cross the unincorporated communities of Castaic and Saugus and the city of Santa Clarita. A total of 300 feet of BLM-managed public lands and four miles of NFS lands would be traversed; however, the new circuit would not require a new or additional ROW. This new circuit would be called Castaic – Haskell Canyon #4 and would utilize the same conductor (bundled 715.5 kcmil "Starling" ACSS/AW [aluminum conductor steel supported/aluminum-clad steel wire]) as that proposed for the new 230 kV transmission line between Barren Ridge and Haskell Canyon Switching Stations.

The addition of a new circuit on existing towers would require many of the same construction activities associated with a new transmission line (refer to Appendix C for a description of each construction activity). However, all work would be within existing ROW and no new towers would be constructed. Some towers may need to be modified or reinforced to carry the additional weight of the new conductor. Specific towers requiring reinforcement would be determined following detailed design of the Project. Tower reinforcement would not alter the general design or the location of the structures. This process would generally include reinforced foundations or steel member replacements. Refer to Figure 1-1 for a map showing the location of the new 230 kV circuit.

1.2.3. Reconductoring of Existing Transmission Line

LADWP proposes the reconductoring of 76 miles of the existing BR-RIN 230 kV transmission line with larger conductors from the Barren Ridge Switching Station to Rinaldi Substation. Four miles of BLM-managed public lands, 13 miles of National Forest System (NFS) lands, and 44 miles of private property would be traversed. The existing conductors (954/ 2,312 kcmil) would be replaced with a new 1,433.6 kcmil "Merrimack" ACSS/TW/HS (aluminum conductor steel supported/trapezoidal wires/high strength) conductor. The new conductor would have a larger diameter that allows for greater electrical capacity.

The upgrade of the existing BR-RIN would also require many of the same activities of the new transmission line (surveying of right-of-way [ROW], rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, and cleanup). Removal of the existing conductor would be used to string a pulling line, and this line would then be used to pull in the new conductor. All work would

remain within the existing 250-foot-wide ROW, with no additional ROW required. Some of the towers would need to be modified, replaced, and/or have foundations reinforced or replaced to carry the additional weight of the new heavier conductor. Refer to Figure 1-1 for the location of the reconductoring.

1.2.4. Construction of New Switching Station

As a component of the BRRTP, LADWP proposes the construction of a new switching station in Haskell Canyon, south of the Angeles National Forest on LADWP-owned property at the convergence of several existing and proposed 230 kV transmission lines (the existing BR-RIN, the proposed double-circuit Barren Ridge – Haskell Canyon, existing Castaic – Northridge, Castaic – Sylmar, Castaic – Olive, and the proposed Castaic – Haskell Canyon). Refer to Figure 1-1 for the location of the new switching station.

The station would be approximately 500 feet by 600 feet to accommodate the necessary circuit positions, which are made up of equipment, such as steel support structures, circuit breakers, disconnect switches, and associated equipment, and a relay house and control house containing control and protective relaying equipment. The relay and control houses would each be approximately 30 feet long by 12 feet wide by 10 feet high and constructed of gray concrete block. The station yard would include a paved internal access road approximately 16 feet wide and would be enclosed by chain-link fencing with barbed-wire extension for security. The preliminary grading plan for the station is located in Appendix C.

Necessary pre-construction geotechnical investigation on-site would include six borings by a drill rig to investigate bedrock and soil stability and four cone penetration test locations after site grading to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

Construction of the new Haskell Canyon Switching Station would consist of preconstruction surveys, clearing and grading of access roads, site grading and drainage development, installation of concrete foundations and steel support structures, installation of below- and above-ground electrical conduits for equipment power and control, installation of below- and above-grade grounding conductors, and installation of control and relay houses. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks, and flatbed trailers. Cranes, man-lifts, portable welding units, line trucks, and mechanic trucks would also be required. Construction would require an estimated 12 months with approximately 60 workers.

Site preparation work for the station would involve clearing and grading of access roads, clearing of the switchyard site, the cut and fill grading of the site, and placement and compaction of structural fill that would serve as a base for switching station facilities. The site would be graded to maintain current drainage patterns as much as possible. A 16-foot-wide paved road and a 100-foot by 100-foot gravel parking area would be required. The yard would be covered with crushed-rock aggregate. Native vegetation would be re-established where possible outside the switchyard fence.

Following site grading and development, reinforced concrete foundations would be installed to support the steel structures and electrical equipment and control facilities. It is estimated that 1,500 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 180 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 120-day working period. Subsequent to the foundation installation, trenches would be dug to facilitate placement of copper conductors for the station grounding mat.

Multiple transmission lines would be terminated into the switching station (i.e., the new and existing Barren Ridge – Haskell and Castaic – Haskell Canyon transmission lines) and would need support and require the installation of galvanized steel structures. An existing 115 kV transmission line may need to

be relocated around the proposed station. High-voltage bus work consisting of aluminum jumpers and tubing would be installed within the station.

1.2.5. Expansion of Existing Switching Station

LADWP proposes expansion of the existing Barren Ridge Switching Station to the east side by 235 feet by 500 feet, for a total station size of 485 feet by 500 feet (approximately 5.6 acres). The expansion area of the station would include electrical structures and equipment for the addition of transmission lines, a material staging area, roadway within the station, and a drainage area. The preliminary design layout for the station may be found in Appendix C. Refer to Figure 1-1 for the location of the existing switching station.

Expansion of the existing switching station would be very similar to the construction of the Haskell Canyon Switching Station as described above. Expansion would consist of preconstruction surveys, site preparation and grading, installation of reinforced concrete foundations, installation of electrical conduits for equipment power and control, and installation of structures and equipment.

Necessary pre-construction geotechnical on-site investigation would include two test pits excavated by a backhoe to investigate soil density and settlement, and four cone penetration test locations on-site to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

It is estimated that 700 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 80 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 90-day working period. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks, and flatbed trailers. Cranes, man-lifts, portable-welding units, line trucks, and mechanic trucks would also be required. An estimated eight months with approximately 60 workers would be required to expand the station.

1.2.6. Project-Wide Mitigation Measures

To address potential impacts of the Proposed Project to multiple resource areas as discussed above, the following project-wide mitigation measure would be applied:

> Three-Circuit Tower Mitigation (THREE-CIRCUIT) – A three-circuit lattice tower design would be implemented as described in Section 1.2.1 of this Technical Report, at the locations shown in Figure 1-7, Three-Circuit Tower Mitigation Map.
>
> Helicopter Mitigation (HELICOPTER) – Helicopter Mitigation shall be implemented, as described in Section 1.2.1 of this Technical Report, in steep areas of the Angeles National Forest where access is limited. For Alternatives 1 and 2a, implementation would occur at the locations shown on Figure 8-2, Identified Helicopter Mitigation Map. During final design of the Project, areas other than those shown on Figure 8-2, including Alternatives 2 and 3, may potentially require helicopter construction of the towers. This determination would generally be made where tower sites have no existing access roads within 300 feet and slopes are greater than 25 percent. Final identification of these tower sites would be determined and agreed upon by USFS, BLM and LADWP.

1.2.7. Construction Work Force and Schedule

The NEPA Record of Decision and CEQA Notice of Determination (anticipated in the early part of 2012) must be made before construction could begin. Therefore, construction of the BRRTP is anticipated to

begin no sooner than summer 2012, with a target in-service date of early 2015. These dates are subject to change based on actual completion of design.

The following construction estimates were based on preliminary engineering and the number of workers and construction duration values are estimates; therefore, they are subject to change based on final engineering and design. The new double-circuit 230 kV transmission line from the Barren Ridge Switching Station to the proposed Haskell Canyon Switching Station would require 12.5 months and 134 workers. The installation of a 230 kV circuit on existing double-circuit towers from the Castaic Power Plant to the proposed Haskell Canyon Switching Station would require a month and a half and 35 workers. The upgrade and reconductoring of the existing BR-RIN would require eight months and 155 workers. The construction of a new 400-foot by 600-foot Haskell Canyon Switching Station would require 12 months and 60 workers. The expansion of the existing Barren Ridge Switching Station would require eight months and 60 workers.

The BRRTP components are anticipated to be constructed in the staggered sequence illustrated below in Tables 1-1 and 1-2. The construction of all Project components would take approximately two years and 447 total workers, with 173 workers at the peak of construction. Table 1-2 summarizes the BRRTP's anticipated construction workforce and schedule based on the most current information available. To allow for any delays in the Project, three weeks of float time were included for the new 230 kV transmission line and reconductoring efforts, and an additional two weeks of float time were included for the stringing of the second circuit between Castaic Power Plant and Haskell Canyon.

TABLE 1-1. ANTICIPATED CONSTRUCTION SEQUENCE

PROJECT COMPONENT	ANTICIPATED CONSTRUCTION SEQUENCE
Expansion of Barren Ridge Switching Station	Weeks 8 – 73
New Haskell Canyon Switching Station	Weeks 1 – 67
New 230 kV Transmission Line	Weeks 42 – 113
Reconductor BR-RIN	Weeks 55 – 88
Addition of 230 kV Circuit	Weeks 51 – 56

TABLE 1-2. CONSTRUCTION WORKFORCE AND SCHEDULE

PROJECT COMPONENT	CONSTRUCTION (START AND END WEEKS)	CONSTRUCTION DURATION (MONTHS)	TOTAL # OF WORKERS	PEAK # OF WORKERS AT ANY GIVEN TIME
Expansion of Barren Ridge Switching Station	8 – 73	15	60	38
New Haskell Canyon Switching Station	1 – 67	15.4	63	38
New 230 kV Transmission Line	42 – 113	16.5	134	131
Reconductor BR-RIN	55 -88	9	155	120
Addition of 230 kV Circuit	51 – 56	1.5	35	35
ALL COMPONENTS	**Weeks 1 – 113**	**26.1 months**	**447 Total Workers**	**173* Peak Workers**

*The value represents the total for the staggered construction of the Project components; it is not reflective of the sum of all the components.

2.0 REGULATORY FRAMEWORK

Primary state guidance relating to principal seismic hazards evaluated in this report is contained in the 1990 Seismic Hazards Mapping Act and 1994 Alquist-Priolo Earthquake Fault Zoning Act (originally enacted in 1972). The Seismic Hazards Mapping Act focuses on potential seismic hazards related to strong ground shaking, liquefaction, and seismically induced landslides. Under provisions in the act, the State is charged with designating and mapping areas at risk for these seismic hazards and the maps and associated reports are to be used by cities and counties in preparing their general plans and adopting land use policies to reduce and mitigate potential hazards to public safety. The California Geological Survey (CGS) has provided Seismic Hazard Zones maps for some quadrangles located in the southern part of the proposed Project area, and these maps are incorporated into this study for evaluation of liquefaction hazard zones and earthquake-induced landslide hazard zones. Some quadrangles in the Project area have not yet been mapped by the State.

Under the Alquist-Priolo Earthquake Fault Zoning Act, the state is charged with delineating "Earthquake Fault Zones" (formerly known as Alquist-Priolo Special Studies Zones) along known active, well-defined faults in California. Cities and counties affected by the zones are to regulate certain development projects for sites within the zones until geologic investigations demonstrate that the sites are not threatened by surface displacement from future faulting. The CGS produces maps delineating Earthquake Fault Zones for quadrangles located in the proposed Project area, and these maps are incorporated into the study for evaluation of potential surface fault rupture related to the active Earthquake Fault Zones in the Project area.

Regulatory agencies responsible for overseeing design and construction of the proposed BRRTP would refer to Seismic Hazards Mapping Act and Alquist-Priolo Earthquake Fault Zoning Act guidelines for evaluation of potential seismic hazards that may affect the Project. In addition to the potential seismic impacts under these guidelines, other potential geologic impacts that may affect the Project would be evaluated during the design and construction phases of the Project, and presented to the regulatory agencies for consideration, as appropriate. Other potential geologic impacts that have been assessed in this preliminary geotechnical evaluation include landslides and mudflows, soil erosion, settlement, expansive soils, corrosive soils, groundwater and dam inundation.

3.0 PROJECT AREA OVERVIEW

The Project study area is bounded by Interstate 5 and the ANF to the west, the Tehachapi Mountains and Piute Mountains to the north, State Highway 14 and the San Gabriel Mountains to the east, and the San Fernando Valley area of Los Angeles to the south (Figure 1). Main physiographic features of the Project area include the Mojave Desert and Antelope Valley area; the San Andreas Rift Zone, which strikes northwesterly through the middle of the Project area; the steep mountainous terrain in the ANF; and the valley areas in the cities of Santa Clarita and San Fernando.

The Mojave Desert and Antelope Valley area is generally comprised of relatively gentle to moderate topographic gradients. Elevations in this part of the Project area range from 2,400 to 3,000 feet above mean sea level (MSL) on the valley floor, and up to 3,200 feet MSL along the flanks of the Tehachapi Mountains. The proposed expanded Barren Ridge Switching Station, proposed Segments A, B, C, E, F, 115th, and the northern portions of Segments D, G, H and I are situated in this part of the Project area (Figure 1).

The San Andreas Rift Zone, associated with movement of the active San Andreas fault, comprises a linear trough of elongate valleys and ridges that crosses about the middle of the Project area oriented in a northwest direction. The rift zone essentially forms a boundary between the Mojave Desert/Antelope Valley area and the ANF/Sierra Pelona mountainous area. Segment D and the northern portion of Segments G, H and I cross the San Andreas Rift Zone. Segment D crosses the rift zone in the western part of the Project study area. Segments G, H and I cross the San Andreas Rift Zone in the Leona Valley in the east part of the study area (Figure 1). The rift zone in the Leona Valley is bounded by Portal Ridge and Ritter Ridge on the northeast. Topographic gradients in this area of the Project range from gentle on the floor of the rift zone trough and Leona Valley to steep on the flanking hillsides including the Portal Ridge and Ritter Ridge areas. Elevations in the San Andreas Rift Zone, Portal Ridge and Ritter Ridge areas range from 3,000 to 3,600 feet MSL.

The ANF part of the Project area generally comprises mountainous areas of gentle to very steep topographic gradients and includes the Sierra Pelona, Liebre Mountain and Bald Mountain. Northeast-trending canyons in the ANF part of the Project area include Liebre Gulch, San Francisquito Canyon, Bouquet Canyon, Mint Canyon, Haskell Canyon and Soledad Canyon. Elevations in the ANF part of the study area range from 1,300 feet MSL in canyon bottoms in the Santa Clarita area, to 4,500 feet MSL on the ridgelines in the Sierra Pelona. Segments G, H, I, J, and the southern portion of Segment D are situated in this part of the Project area. The proposed Haskell Canyon Switching Station is located in this part of the Project area at the northern end of Haskell Canyon (Figure 1).

The southern part of the Project area is situated between the Santa Clarita Valley and San Fernando Valley, which comprise areas of relatively gentle to moderate topographic gradients, and includes steep topographic gradients in the San Gabriel Mountains between these valleys. Elevations range from 1,300 feet MSL to 1,500 feet MSL in the Santa Clarita valley area; from 1,500 feet MSL to 2,300 feet MSL in the San Gabriel Mountains between the valleys; and from 1,000 feet MSL to 1,500 feet MSL in the northern San Fernando Valley. Segment K for the proposed reconductoring of the existing 230kV line from the new Haskell Canyon location to Rinaldi is located in this part of the Project area.

4.0 INVENTORY METHODS

To develop a geologic inventory for the proposed BRRTP, this preliminary geotechnical evaluation has included review of soil, geologic and seismic background information and field reconnaissance for assessment of potential geologic and seismic hazards and potential geologic impacts associated with implementation of the Project in the study area. A review of geotechnical background data, geologic maps, topographic maps, regional fault maps, seismic data, soil data, groundwater data, GIS data, and aerial photography was performed to assess the general geologic and seismic conditions within the Project study area and underlying the proposed route corridors and switching stations. Field reconnaissance was performed of accessible areas of the Project components to observe general geologic site conditions, map pertinent geologic features, and check the overall aerial geology presented on geologic maps. Compilation and analysis of the data obtained were performed to evaluate potential Project impacts and develop recommendations for mitigation, as appropriate.

Geologic maps, data and literature published by the CGS, formerly the California Division of Mines & Geology (CDMG), have been incorporated as part of this study for evaluation of the Project area geology, distinctive geologic features, faults, potential liquefaction hazard zones and earthquake-induced landslide hazard zones, mapped landslide or mudflow areas, and groundwater. Data and information from the Southern California Earthquake Center (SCEC) have been utilized for information related to faults. Groundwater data from the California Department of Water Resources (CDWR), where available, have been utilized for evaluation of groundwater levels in the Project study area. Regulations within the California Building Code (CBC) are considered for potential design mitigation recommendations. Geotechnical-related portions of the California Environmental Quality Act (CEQA) have been utilized as a guideline for this evaluation.

Seismic data published by the United States Geological Survey (USGS) have been incorporated in this study for evaluation of potential ground shaking levels in the Project study area. GIS data for potential ground shaking levels were utilized. Topographic maps published by the USGS have been reviewed as part of this study for evaluation of elevations and topographic gradients in the Project area. Soil data from the United States Department of Agriculture (USDA) National Resource Conservation Service (NRCS) have been utilized to evaluate USDA soil classifications, potential soil erosion, expansive soils and corrosive soils. Geotechnical-related portions of the Safety Elements of the Los Angeles County General Plan and Kern County General Plan have been incorporated into this study for evaluation of potential subsidence, and dam failure and seiche inundation hazard areas. Background documents reviewed are presented in the References.

Field reconnaissance of the proposed segments and switching stations sites was performed to supplement the background literature study for this evaluation. Field reconnaissance was limited to portions of segments in the Project area accessible by vehicle on existing transmission line and other access roads. The visual reconnaissance was made to observe general geologic site conditions and topographic conditions, observe conditions of existing transmission line improvements, map pertinent geologic features, and check the general geologic mapping presented on geologic references. Observations were made of the siting area for the proposed Haskell Canyon Switching Station and of the proposed expanded Barren Ridge Switching Station. Field observations were generally made in accessible areas within an approximate ½-mile-wide study corridor along the proposed routes. The field reconnaissance was further supplemented by aerial (helicopter) reconnaissance photographs and notes provided by LADWP geologists for inaccessible portions of some segments of the Project.

5.0 AFFECTED ENVIRONMENT

5.1 REGIONAL GEOLOGIC SETTING

The Project study area is located within two geomorphic regions, or "provinces," characterized by the morphology of the landforms, the general type and age of the geologic materials, and by the tectonic-structural features of the geology in the region. The Transverse Ranges Geomorphic Province and Mojave Desert Geomorphic Province that include the study area are divided by the northwest-trending San Andreas fault zone. The Antelope Valley, Mojave Desert and Barren Ridge part of the study area northeast of the San Andreas fault is located in the western corner of the Mojave Desert Province. The part of the study area southwest of the San Andreas fault, including the ANF, Sierra Pelona, and the cities of Santa Clarita and San Fernando, is within the Transverse Ranges Province.

The Mojave Desert Geomorphic Province is characterized by mountain ranges and hills of moderate relief that are partially buried and separated by broad alluviated basins like the Antelope Valley (Norris and Webb, 1990). This province is bounded in the study area by the San Andreas fault on the southwest and by the Garlock fault on the northwest, forming a triangular-shaped region on the west side of this province. The Mojave Desert Province extends east from the study area. The Transverse Ranges Geomorphic Province is characterized by east-west trending mountain ranges and fault systems (Norris and Webb, 1990). The province is bounded on the northeast by the San Andreas fault, and extends west and south from the study area.

5.2 STUDY AREA GEOLOGIC SETTING

The mountain ranges and hills of the Project study area are comprised primarily of Tertiary age (2 to 65 million years old) marine and non-marine sedimentary and volcanic rocks; Mesozoic era (65 to 245 million years old) granitic rocks; and Paleozoic era (245 to 570 million years old) metamorphic and granitic rocks including schist, gneiss and limestone. Younger Quaternary age (last 1.6 million years) alluvium and other sediments underlie low-lying valley and canyon bottoms, and much of the Mojave Desert and Antelope Valley parts of the study area. A regional geologic map of the study area is shown on Figure 2.

The older, pre-Tertiary age crystalline basement rocks typically comprise granite, quartz monzonite, gabbro, schist, gneiss, and other igneous and metamorphic rocks. Younger Tertiary age volcanic and sedimentary formations of marine and non-marine origin that overlie the basement rocks contain units of sandstone, siltstone, shale, conglomerate, and undifferentiated pyroclastic and intrusive volcanic rocks. Younger Quaternary age alluvium and other deposits overlie the bedrock in the Mojave Desert and Antelope Valley, and other valleys, canyon bottoms and low-lying drainage areas in the study area.

The Quaternary deposits are generally subdivided into two stratigraphic units according to relative age: older Pleistocene (11,000 to 2 million years ago) age deposits, and younger Holocene deposits (last 11,000 years). Older Pleistocene age alluvial deposits generally consist of gravel, sand, silt, and clay that is moderately to well consolidated and often slightly cemented. These materials include older alluvial fan deposits in the Mojave Desert and Antelope Valley, continental terrace deposits, and older lacustrine (lake) or playa deposits. Holocene deposits typically consist of relatively young, poorly consolidated or unconsolidated silt, sand and gravel alluvium, and are anticipated to be present in the study area in washes, valley bottoms, and lakebeds. The Holocene deposits can also include eolian (wind-blown) sands, colluvial (slopewash) deposits, residual soils, and agricultural and fill soils from farming, grading or other man-made activities in the Project area.

In general, the distribution of geologic units in the Project study area, as shown on Figure 2, is such that much of the northern half of the Project study area in the Antelope Valley and Mojave Desert is underlain by Quaternary alluvial sediments. Much of the southern half of the Project study area in the mountainous ANF and Sierra Pelona is underlain by older Tertiary and pre-Tertiary rock formations, with the exception of canyon bottoms and other drainage areas comprising alluvium. The geologic units mapped in the Project area are described in further detail in Table 1, and are listed by geologic symbol for the corridor segments on a 1/10th mile basis in Appendix A.

TABLE 1 – PRINCIPAL GEOLOGIC UNITS IN THE PROJECT STUDY AREA

GEOLOGIC SYMBOL[1]	GEOLOGIC UNIT	DESCRIPTION
Qs	Dune Sand	Recent wind-blown sand (eolian) deposits.
Qa	Alluvium	Unconsolidated, poorly sorted alluvial clay, silt, sand and gravel sediments. Includes fan, flood plain, and streambed deposits; and includes mixture of playa clay and wind-blown sand in some desert areas.
Qpc	Plio-pleistocene non-marine	Varied sedimentary rocks of non-marine origin including shale, siltstone, sandstone, conglomerate and breccia.
Tc, Mc, Oc	Tertiary non-marine	Varied sedimentary rocks of non-marine origin including clay shale, mudstone, siltstone, sandstone, fanglomerate and breccia.
P, M, E, Ep	Tertiary marine	Varied sedimentary rocks of marine origin including shale, mudstone, siltstone, sandstone, and conglomerate.
Ti, Tv, Tvp	Volcanic rocks	Undifferentiated volcanic rocks including rhyolite, andesite, basalt, and pyroclastic rocks; and intrusive volcanic (hypabyssal) rocks of similar composition.
gr-m	Granitic and metamorphic rocks	Undifferentiated gneisses and granitic rocks.
gb, grMz, grPz, grpC	Granitic rocks	Granitic rocks including quartz monzonite, granodiorite, quartz diorite, diorite, gabbro, and anorthosite.
ls/PZ	Paleozoic	Sedimentary and metasedimentary limestone, dolomite and marble. Lenses of marble in granitic and metamorphic rocks in the Tehachapi Mtns.
sch	Schist	Highly foliated, mica-rich schist (Pelona Schist).
m	Metasedimentary rocks	Biotite gneiss, mica schist, quartzite and hornfels.
pC	Gneiss	Coarse and fine augen gneisses, amphibolite, hornfels, diorite and granite gneiss.

Notes: [1] Symbol used on Figure 2.

5.3 SEISMICITY

The Project study area is situated within a seismically active region of southern California, and numerous active and potentially active faults have been mapped within or adjacent to the study area. As defined by the CGS, an active fault is one that has had surface displacement within Holocene time (roughly the last 11,000 years). Potentially active faults are those that show evidence of surface displacement during Quaternary time (roughly the last 1.6 million years) but for which evidence of Holocene movement has not been established. An inactive fault is one that has not shown evidence of surface displacement during Quaternary time.

The approximate locations of the principal active faults in the region and their geographic relationship to the study area are shown on Figure 3. Table 2 lists nearby principal faults, the maximum moment magnitude (M_{max}), the fault type, the slip rate, the fault source type, and significant historic earthquakes that have occurred on the faults.

TABLE 2 – PRINCIPAL REGIONAL ACTIVE AND POTENTIALLY ACTIVE FAULTS

FAULT	APPROXIMATE DISTANCE TO NEARBY SEGMENT (SEGMENT) (miles) [1]	MAXIMUM MOMENT MAGNITUDE (M_{max}) [2]	FAULT TYPE[2]	SLIP RATE (mm/yr) [2]	SIGNIFICANT HISTORIC EARTHQUAKES[3]

Principal active faults in the region that may affect the site are described below:

San Andreas Fault Zone

The San Andreas fault zone has long been recognized as the dominant seismotectonic feature in California. This active, right-lateral, strike-slip fault is over 700 miles long and strikes northwest through the state from the Gulf of California to north of San Francisco. Two of California's three largest historic earthquakes, the 1906 San Francisco earthquake and the 1857 Forth Tejon earthquake, occurred along the San Andreas fault (SCEC, 2004). The slip rate of the fault is estimated to be 30 millimeters (mm) per year (Cao, 2003). The fault is considered capable of producing earthquakes in excess of M_{max} 7.4, and the average frequency of earthquakes along this segment of the San Andreas fault is 140 years (SCEC, 2004). The San Andreas fault crosses Segments D, G, H and I through the middle of the Project study area, oriented in a northwesterly direction (Figure 3).

Garlock Fault Zone (West)

The Garlock fault zone is a prominent fault feature in southern California and strikes northeast across the northern part of the Mojave Desert province. Although this fault has not produced large earthquakes historically, geomorphic and stratigraphic evidence indicates that it has done so in the past. The Garlock (West) fault is considered capable of generating about a M_{max} 7.3 earthquake. A portion of the Garlock fault zone near the Project study area ruptured due to the 1952 Kern County Earthquake that occurred on the White Wolf Fault (SCEC, 2004). A total of about 30 to 40 miles of left-lateral, strike slip has been documented across the Garlock (West) fault, and the slip rate is estimated to be 6 mm per year. The Garlock (West) fault zone crosses Segment A at the northern end of the segment near Barren Ridge.

San Fernando Fault Zone

The San Fernando fault zone is a zone of thrust faulting and ground rupture areas related to the 1971 San Fernando earthquake, and is located in the Sunland and San Fernando area of the San Fernando Valley (SCEC, 2004). The zone is 10 miles long, has an estimated slip rate of 5 mm per year, and is considered capable of generating about a M_{max} 6.8 earthquake (SCEC, 2004). The San Fernando fault zone crosses the southern end of Segment K in the San Fernando area.

Santa Susana Fault

The Santa Susana fault is a thrust fault 23 miles long located near the communities of Piru, Sylmar, and San Fernando. A short segment of the fault ruptured slightly during the 1971 San Fernando earthquake (SCEC, 2004). The Santa Susana fault is considered capable of generating about a M_{max} 6.7 earthquake. The slip rate of the fault is estimated to be 5 mm per year. The Santa Susana fault is located near the south end of the Project study area west of the Rinaldi substation.

San Gabriel Fault Zone

Segments of the San Gabriel fault zone are described as potentially active, and a portion of the fault between Castaic and Saugus is described as active (Jennings, 1994). This right-lateral, strike-slip fault is considered capable of producing a M_{max} 7.2 earthquake. The San Gabriel fault has a total length of 87 miles, and the slip rate of the fault is estimated to be 1 mm per year. The San Gabriel fault zone crosses Segment K.

Sierra Madre Fault Zone

The Sierra Madre fault zone is composed of a series of active reverse faults. The 35-mile-long fault zone is located between the cities of Sunland and Azusa along the foothills of the San Gabriel Mountains. The Sierra Madre fault is considered capable of generating about a M_{max} 7.2 earthquake. The slip rate of the fault is estimated to be 2 mm per year. The Sierra Madre fault is located southeast of the Project study area.

White Wolf Fault

The White Wolf fault is an active, left-lateral reverse fault located northwest of the Project study area near the community of Tehachapi. The White Wolf fault was the source of one of the largest earthquakes in Southern California history, the 1952 M 7.5 Kern County earthquake (SCEC, 2004). The Tehachapi area reportedly experienced extensive property damage due to the 1952 Kern County earthquake (Kern County, 2005). The White Wolf fault is considered capable of generating about a M_{max} 7.5 earthquake. The fault is 37 miles in length and has an estimated slip rate of 2 mm per year.

Pleito Thrust Fault Zone

The Pleito Thrust fault zone is a south-dipping, active thrust fault that is part of a complex zone of thrust faults and folds which mark part of the southern end of the Central Valley of California. The Pleito thrust may be connected at depth with the nearby, and similar, Wheeler Ridge fault. At the eastern end of the fault, it may dive below the surface as a blind thrust, forming the northern scarp of the Tehachapi Mountains (SCEC, 2004). The Pleito thrust is considered capable of generating about a M_{max} 7.0 earthquake, and has an estimated slip rate of 2.0 mm per year (Cao, 2003). The Pleito thrust fault zone is 28 miles in length is located west of the Project study area.

Lenwood-Lockhart-Old Woman Springs Faults

The Lenwood, Lockhart, and Old Woman Spring faults are right-lateral, strike-slip faults that form a connected, fairly complex, fault system 99 miles long (SCEC, 2004). The Lenwood-Lockhart-Old Woman Spring fault system is considered capable of generating about a M_{max} 7.5 earthquake. The slip rate of the fault is estimated to be 0.6 mm per year (Cao, 2003). Portions of this fault system located in the Mojave Desert east of Barren Ridge are considered active (Jennings, 1994).

Helendale-South Lockhart Faults

The active Helendale fault is a right-lateral, strike-slip fault about 56 miles in length and may form a roughly continuous fault system with the active South Lockhart fault located east of Barren Ridge in the study area (SCEC, 2004). This fault system is considered capable of producing a M_{max} 7.3 earthquake. The slip rate of the fault is estimated to be 0.6 mm per year (Cao, 2003). The Helendale-South Lockhart faults are located in the Mojave Desert east of the Project study area.

San Cayetano Fault

The San Cayetano fault is a thrust fault 28 miles long located near the communities of Piru, Fillmore, and Ojai. The San Cayetano fault is considered capable of generating about a M_{max} 7.0 earthquake. The slip rate of the fault is estimated to be 6 mm per year. The San Cayetano fault is located west of the Project study area.

Malibu-Santa Monica-Raymond Fault Zone

The Malibu Coast, Santa Monica, Hollywood, and Raymond faults are considered a fault zone that is a subsystem of the Transverse Ranges Southern Boundary fault system (Dolan, et al, 2000). The fault zone extends sub-parallel to the Malibu coastline easterly along the south side of the Santa Monica Mountains through Malibu, Santa Monica, West Los Angeles, and Hollywood. The fault system exhibits reverse left-lateral movement and is considered capable of generating earthquakes ranging from M 6.4 to 6.7 in the Project area (Cao, 2003).

5.4 DATA INVENTORY RESULTS - SEGMENTS

5.4.1. Geologic Resources

Soils

Soils are present at the ground surface along the majority of the proposed Project segments except in locations where rock formations are exposed. In a general sense, deeper soils are present in the valleys and other low-lying areas of the Project, and shallow soils are present in the mountainous parts of the Project study area. The soils underlying the proposed Project segments are comprised of variable material types from gravel and sand to silt and clay, and are generally reflective of the underlying geologic unit, extent of weathering, degree of slope, and the degree of human modification. The proposed Project segments traverse varied terrain and land areas comprised of undeveloped desert and mountain areas, agricultural land, developed rural properties, and developed urban areas consisting of industrial, commercial and residential uses.

In order to inventory the soils underlying the Project segments, data from the NRCS was evaluated. Soil surveys from the NRCS utilized for the evaluation included Kern County, Southeastern Part (CA670), Antelope Valley Area (CA675), ANF (CA776), and Los Angeles County, West San Fernando Valley (CA676). More than 125 soil types are mapped underlying the proposed Project segments, and an inventory of these individual soils, including a general description of the soil, the soil erodibility potential, shrink-swell potential, and corrosion potential, is provided for the segments on a 1/10th mile basis on the USDA Soil Table in Appendix B. A summary of NRCS U.S. General Soil Types (soil families) for each segment and for the switching stations is presented in Table 3, and is shown on the Regional Soils Map on Figure 4.

TABLE 3 – SUMMARY OF U.S. DEPARTMENT OF AGRICULTURE U.S. GENERAL SOIL TYPES[1]

SEGMENT/LOCATION	U.S. GENERAL SOIL TYPES

Distinctive Geologic Features

This geologic resource refers to the potential existence of distinctive, prominent geologic features, which may have beneficial aesthetic or scientific characteristics. Distinctive geologic features can include unique marker beds, scenic rock formations or significant outcrops. In addition to the positive aesthetic characteristics of distinctive rock formations, these features provide access for geologists and the public to observe and study the underlying rock formation or geologic structure of an area where it may otherwise be concealed by soil cover.

Based on background review and limited field reconnaissance, there are distinctive geologic features that are present in some of the rock formations in the Project study area. Geologic features traversed by the proposed segments in the BRRTP study area that are considered distinctive include white tuff (volcanic ash) marker beds that are mapped in the Bouquet Canyon/Vasquez Canyon area along Segment I. The white tuff marker beds that are present along Segment I are considered a distinctive aesthetic feature due to their white color and the characteristic formation that outcrops (juts out of the ground) in the Bouquet Canyon/Vasquez Canyon bottom. This rock unit is also reported to contain vertebrate fossils. The evaluation of this rock unit as a paleontological resource is provided in the paleontological technical report.

Rock formations in the Project study area are present in the southern part of Segment D, and in Segments G, 2a, H, I, J, and portions of Segment K. The majority of these geologic formations contains more common rock outcrops, exposed road cuts and soil-covered areas, and is not considered highly distinct. However, distinctive geologic features may be present in limited areas of some rock formations in the Project study area not indicated on geologic maps or observed during field reconnaissance. The Mojave Desert and Antelope Valley portions of the Project, and other low-lying valley areas with alluvium and soil cover do not comprise rock formations at the ground surface and do not contain distinctive geologic features.

Distinctive geologic features were not observed at the location of the proposed expanded Barren Ridge Switching Station and were not observed at the site of the proposed Haskell Canyon Switching Station. A summary of distinctive geologic features is presented in Table 4, and is provided for the corridor segments on a 1/10th mile basis on the Impact Assessment Table in Appendix A.

TABLE 4 – SUMMARY OF DISTINCTIVE GEOLOGIC FEATURES

SEGMENT	DISTINCTIVE GEOLOGIC FEATURES[1]
A	None
B	None
C	None
D	None
E	None
F	None
115th	None
G	None
2a	None
H	None
I	White tuff marker beds from mileposts 27.0 to 27.1, 28.6 to 28.9
J	None
K	None

5.4.2. Geologic and Seismic Hazards

Surface Fault Rupture

Surface fault rupture is the offset or rupturing of the ground surface by relative displacement across a fault during an earthquake. Evaluation of the potential hazard of surface fault rupture is based on the concepts of recency and recurrence of faulting along existing faults. In general, the more recent the faulting, the higher the probability for future faulting (Allen, 1975). Faults of known historic activity during the last 200 years, as a class, have a higher probability for future activity than faults classified as Holocene age (last 11,000 years) and a much higher probability of future activity than faults classified as Quaternary age (last 1.6 million years). However, it should be kept in mind that certain faults have recurrent activity measured in tens or hundreds of years whereas other faults may be inactive for thousands of years before being reactivated. The magnitude, sense, and nature of fault rupture also vary for different faults or even along different strands of the same fault. Even so, future faulting generally is expected to recur along pre-existing faults (Bonilla, 1970). The development of a new fault or reactivation of a long-inactive fault is relatively uncommon and generally is not a consideration in project development.

There is a probability for surface fault rupture to occur across the proposed Project segments along the more recent, historically active faults, particularly the active San Andreas fault zone, Garlock fault zone and San Fernando fault zone. The segment of the San Andreas fault that ruptured during the 1857 Fort Tejon earthquake is located in the Project study area. Ground surface offset as much as 30 feet was reported across the fault due to that earthquake. Other active and potentially active faults in the Project study area may also have potential for surface rupture due to seismic activity. During an earthquake on these active or potentially active faults within the Project area, potential surface rupture of the fault may result in relative displacement of the ground across the fault surface.

Some proposed segments of the BRRTP are located within a State of California Earthquake Fault Zone for the potential for ground surface rupture due to active faults. Earthquake Fault Zones within the proposed Project area are related to active faults that include the San Andreas fault zone crossed by segments D, G, H and I; the Garlock (West) fault zone crossed by Segment A near Barren Ridge; and splays of the San Fernando fault zone under Segment K located in the San Fernando Valley. The proposed Haskell Canyon and expanded Barren Ridge switching stations are not located in an Earthquake Fault Zone. Earthquake Fault Zones within the Project study area are shown on Figure 5.

A summary of Earthquake Fault Zones is presented in Table 5, and is provided for the corridor segments on a 1/10th mile basis on the Impact Assessment Table in Appendix A.

TABLE 5 – SUMMARY OF EARTHQUAKE FAULT ZONES

SEGMENT	EARTHQUAKE FAULT ZONES[1]

Notes:
[1] Hart and Bryant, 1997 (formerly Alquist-Priolo Special Studies Zones).

Seismic Ground Shaking

Seismic ground shaking is the response of the surface to the passing of earthquake wave fronts radiating from the focus of the earthquake. The period of shaking corresponds with the passage of the seismic wave through the site. Earthquake events from one of the regional active or potentially active faults within or near the study area could result in strong ground shaking which could affect the Project study area. The level of ground shaking at a given location depends on many factors, including the size and type of earthquake, distance from the earthquake, and subsurface geologic conditions. Disregarding local variations in ground conditions, the intensity of shaking at different locations within the study area can generally be expected to decrease with distance away from an earthquake source. The size and type of construction also affects how particular structures perform during ground shaking.

In order to evaluate the level of ground shaking that might be anticipated along the proposed Project segments due to the extent of the area, estimated peak horizontal ground acceleration (PGA) data available from the USGS was reviewed (USGS, 2002). These data indicate that the Project study area is located in an area where PGA ranging from 0.25g to 0.80g (25 to 80 percent of the acceleration due to gravity) would be anticipated during an earthquake. Higher ground acceleration levels are attributable to higher levels of ground shaking. Estimated PGA contours in the study area are presented on Figure 6. A summary of potential ground shaking levels for each segment is presented in Table 6, and is provided for the corridor segments on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

In order to evaluate the level of ground shaking that might be anticipated at the proposed new Haskell Canyon Switching Station and expanded Barren Ridge Switching Station, site-specific analysis was performed. The 2007 California Building Code (CBC) recommends that the design of structures be based on the horizontal PGA having a 2 percent probability of exceedance in 50 years which is defined as the Maximum Considered Earthquake (MCE). The statistical return period for PGA_{MCE} is roughly 2,475 years. The probabilistic PGA_{MCE} for the switching stations was calculated as a percentage of gravity's acceleration using the USGS ground motion calculator (USGS, 2008). Using the USGS ground motion calculator, the design PGA for the proposed Haskell Canyon Switching Station was 0.40g and the design PGA for the expanded Barren Ridge station was 0.52g. The potential ground shaking levels for the switching stations are also presented in Table 6. The estimates of ground motion do not include near-source factors that may be applicable to the design of structures on site. The requirements of the governing jurisdictions and the 2007 CBC should be considered in Project design.

TABLE 6 – SUMMARY OF GROUND SHAKING POTENTIAL

SEGMENT	APPROXIMATE GROUND SHAKING POTENTIAL[1], (% OF THE ACCELERATION DUE TO GRAVITY)
A	0.30 g
B	0.25 – 0.40 g
C	0.30 g
D	0.30 – 0.60 g
E	0.30 – 0.40 g
F	0.40 – 0.60 g
115th	0.40 – 0.60 g
G	0.40 – 0.80 g
2a	0.60 – 0.80 g
H	0.40 – 0.60 g
I	0.40 – 0.80 g
J	0.40 g
K	0.40 – 0.80 g

Notes:

Liquefaction

Liquefaction is a phenomenon in which soil loses its shear strength for short periods during an earthquake. Ground shaking of sufficient duration can result in the loss of grain-to-grain contact, due to a rapid increase in pore water pressure, causing the soil to behave as a fluid for short periods. To be susceptible to liquefaction, a soil is typically cohesionless, with a grain size distribution of a specified range (generally sand and silt), loose to medium dense, below the groundwater table, and subjected to a sufficient magnitude and duration of ground shaking.

The State of California Seismic Hazards Mapping Program produces maps identifying potential liquefaction hazard zones, and has produced these maps for some quadrangles within the Project study area Many quadrangles within the study area have not been mapped by the State. Potential liquefaction hazard zones underlying proposed route segments in the study area that have been mapped by the State are shown on Figure 7. The label "edge of data" on Figure 7 delineates the boundary between the quadrangles that have available data and those that do not. A summary of potential liquefaction zones is presented in Table 7, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

Review of the state maps and data indicate that portions of some segments of the Project are underlain by potential liquefaction zones. These areas are located in the southern part of the Project area and include stream, valley and canyon bottoms, typically where liquefaction-prone conditions are present (loose granular soils and shallow groundwater). Areas with potential liquefaction zones include the low-lying canyons and valleys in the ANF, southern Antelope Valley, Leona Valley, the city of Santa Clarita and the San Fernando Valley. Consequently, these mapped areas and other areas with similar geologic conditions in the study area have the potential for liquefaction to occur. The potential hazard of liquefaction is not a consideration for portions of the Project study area underlain by shallow bedrock, which is typical of the mountainous ANF and Sierra Pelona areas. The proposed Haskell Canyon and expanded Barren Ridge switching stations are not located in a liquefaction hazard zone.

Notes:

[1] Data from CGS Seismic Hazards Mapping Program. Data not available for some quadrangles in the Project study area.

Landslides

Landslides typically occur in areas of steep slopes where underlying earth materials are relatively weak and particularly where high rainfall occurs and/or high groundwater levels are present. Landslides can consist of rockfalls, shallow slumps, mudflows and erosional failures, or deeper-seated rotational and block failures. Shallow failures are typically caused by high incident rainfall or concentrated surface runoff conditions that weaken surficial materials. Rotational slides, block-type slides and rockfalls form deeper within the ground, typically within rock formations, and are generally related to discontinuities in the rock that manifest into a sliding surface. Rainfall and other water infiltration into the ground can exacerbate and trigger these deeper sliding conditions. Ground shaking due to earthquakes can cause landslides to develop, trigger incipient landslides or reactivate ancient landslides.

Geologic maps produced by Thomas W. Dibblee that are available for quadrangles in the mountainous southern portion of the Project study area were reviewed for mapped landslides located within the study corridors. In addition, landslide maps contained in the State of California Seismic Hazards Reports were reviewed for mapped landslides located within the study corridors. Based on review of these referenced geologic maps of the Project study area, some existing landslides are mapped within the 500-foot-wide study corridors for the proposed segments. The State of California Seismic Hazards Mapping Program produces maps identifying potential earthquake-induced landslide hazard zones, and has produced these maps for some quadrangles within the Project study area. Many quadrangles within the study area have not been mapped by the State.

Areas of mapped landslides and earthquake-induced landslide hazard zones are predominantly located in the southern part of the Project area in the mountainous areas of the ANF and Sierra Pelona. Landslides are more likely to occur in these areas where steep slopes are present. Consequently, these mapped areas and other areas with similar steep slope conditions in the study area have potential for landslides and earthquake-induced landslides to occur. The potential for landslides and earthquake-induced landslides is not a consideration for portions of the study area with gentle to moderate topographic gradients, including much of the Antelope Valley, Mojave Desert and low-lying valley areas.

Mapped landslides are shown on the Mapped Landslide Inventory map, Figure 8. Potential earthquake-induced landslide hazard zones underlying proposed route segments in the study area that have been mapped by the State are shown on Figure 9. The label "edge of data" on Figure 9 delineates the boundary between the quadrangles that have available data and those that do not. A summary of mapped landslides and earthquake-induced landslide hazard zones traversed by each segment is presented in Table 8, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A. Landslides are mapped and were observed in the vicinity of the proposed Haskell Canyon Switching Station. The Barren Ridge Switching Station is located on relatively level ground on the Mojave Desert floor, and landslides are not present. The switching station sites are not located in an earthquake-induced landslide hazard zone.

TABLE 8 – SUMMARY OF MAPPED LANDSLIDES AND EARTHQUAKE-INDUCED LANDSLIDE HAZARD ZONES

Soil Erosion

Erosion refers to the process by which soil or earth material is loosened or dissolved and removed from its original location. Erosion can occur by varying processes and may occur in the Project area where bare soil (or rock) is exposed to wind or moving water (both rainfall and surface runoff). The processes of erosion are generally a function of material type, terrain steepness, rainfall or irrigation levels, surface drainage conditions, and general land uses. Review of geologic maps and soil data indicate that surface soils along the proposed segments are comprised of variable types of materials. In addition, the proposed segments follow varied topographic terrain ranging from gentle to steep gradients. In a general sense, steeper slope gradients provide a higher erosion potential, for similar soil types. Potential erosion of surface soils is exacerbated when saturated by rain or heavy irrigation.

Many surface soils along the proposed route segments are primarily comprised of sands with variable amounts of gravel, and some fine-grained silt and clay soils. Sandy soils typically have low cohesion, and have a relatively higher potential for erosion from surface runoff when exposed in cut slopes or utilized near the face of fill embankments. These types of sandy soils are present in much of the alluvial areas in the Antelope Valley/Mojave Desert area, and in many low-lying drainage areas of other parts of the Project. Surface soils with higher amounts of clay tend to be less erodible as the clay acts as a binder to hold the soil particles together. Hard rock formations, such as in the mountainous areas of the Project, tend to be less erodible due to the lithified nature of rock.

In order to evaluate the erosion potential of the soils underlying the Project alignments, data from the NRCS was evaluated. The data pertain to the potential hazard of erosion to "off-road" and "off-trail" areas along the proposed Project segments from ground disturbance due to Project construction. The erosion hazard ratings apply to the potential for sheet or rill erosion in areas where 50 to 75 percent of the areas have been exposed by ground disturbance, such as grading for access roads and tower sites. Potential areas of erosion for the Project have been categorized as slight, moderate, severe and very severe (USDA, 2008d), and are shown on Figure 10. A summary of the erosion potential of surface soils along the proposed corridor segments is presented in Table 9, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

The soil erosion potential at the proposed Haskell Canyon Switching Station has been categorized as severe. The soil erosion potential at the expanded Barren Ridge has been categorized as slight.

TABLE 9 – SUMMARY OF EROSION POTENTIAL AREAS TRAVERSED BY EACH SEGMENT[1]

SEGMENT	LENGTH OF SEGMENT (MILES)	SLIGHT EROSION POTENTIAL (MILES)	MODERATE EROSION POTENTIAL (MILES)	SEVERE TO VERY SEVERE EROSION POTENTIAL (MILES)
A	13.2	13.2	0.0	0.0
B	26.5	25.9	0.0	0.6
C	21.7	21.5	0.2	0.0

H	19.8	2.2	1.6	16.0
I	31.9	5.3	7.0	19.6
J	12.0	0.3	0.4	11.6
K	15.4	0.9	0.4	8.8

Notes:

[1]Data from USDA(2008d); Data for some portions of Segment K is not available.

Subsidence

Subsidence is characterized as a sinking of the ground surface relative to surrounding areas, and can generally occur where deep alluvial soil deposits are present in valley areas such as the Antelope Valley, the city of Santa Clarita and the San Fernando Valley. Subsidence in alluvial valley areas is typically associated with groundwater withdrawal or other fluid withdrawal from the ground such as oil and natural gas. These geologic components can cause subsidence, which can result in the development of ground cracks, which could cause damage to the proposed transmission lines, including foundations, structures, pavements, and other hardscape features. Historical subsidence may have occurred in some of the valleys of the Project study area; however, the background review did not indicate that subsidence has been recently reported. No subsidence-induced ground cracks were observed crossing the proposed Project segments or switching station sites. Damage to existing transmission lines in these areas was not reported.

Soil Settlement

Loose natural soils or undocumented/poorly compacted fill may be present in some areas at the site. Much of the study area is mantled by young alluvial soils, which are generally poorly consolidated, reflecting a history without substantial loading. The older alluvial deposits present in the study area are generally relatively dense or weakly cemented and are typically less compressible than the young alluvial soils. However, older alluvial deposits may include potentially collapsible layers above the groundwater table. Collapsible soils are distinguished by their potential to undergo a significant decrease in volume upon an increase in moisture content, even without an increase in external loads.

Portions of the Project study area contain existing fill soils associated with roadway construction, property and structure development, utilities, and other factors. The degree of compaction, material types, and underlying ground conditions of existing fill soils in the study area is unknown. Undocumented or poorly compacted fill may be present in these areas. In addition, the proposed route segments transition between highly variable materials ranging from loose soils to hard rock, and the potential for differential ground movement can exist at these transitions.

Detailed references regarding the potential for settlement/collapse of soils in the Project study area are not available. The potential for soils prone to settlement or collapse would be evaluated on a site-specific basis during the design phase of the Project.

Expansive Soils

Expansive soils may be present in geologic units that underlie the proposed Project segments. Expansive soils are characterized by their ability to undergo significant volume change (shrink or swell) due to variations in moisture content. Earth materials susceptible to these volumetric changes include soils and rock formations containing clays. Changes in soil moisture content can result from rainfall, irrigation, pipeline leakage, surface drainage conditions, perched groundwater, drought, or other factors. Volumetric change of expansive soil may cause excessive cracking and heaving of structures with shallow foundations, concrete slabs-on-grade, or pavements supported on these materials.

Due to the extent of the proposed Project segments, and lack of site-specific geologic references regarding the presence of expansive soils in the Project study area, USDA soil data from the NRCS was utilized to evaluate the presence of expansive soils. The NRCS data are limited to some soils that are present along the proposed Project segments, and expansive soils may be present in other areas of the Project not indicated by the NRCS data.

Linear extensibility percent is the method used by the NRCS to evaluate the shrink-swell potential of soils, and refers to the change in length of an unconfined clod as moisture content is decreased from a moist to a dry state. The volume change is reported as percent change for the whole soil. The shrink-swell (expansion) potential is low if the soil has a linear extensibility of less than 3 percent; moderate if 3 to 6 percent; high if 6 to 9 percent; and very high if more than 9 percent (USDA, 2007a). If the linear extensibility is more than 3 percent, shrinking and swelling can cause damage to buildings, roads, and other structures.

The linear extensibility data in the Project study area are limited to a few soil types. A summary of the expansive potential of surface soils along the proposed corridor segments, where available from the NRCS data, is presented in Table 10, and is presented on a 1/10th mile basis in the USDA Soil Table in Appendix B. NRCS data regarding the expansive potential of surface soils at the proposed Haskell Canyon Switching Station have not been reported. However, based on the nature of the earth units mapped at the site and observed during the reconnaissance (clay shale and sandstone units), moderately to highly expansive soils may be present at this site. USDA data regarding the expansive potential of surface soils at the expanded Barren Ridge Switching Station have not been reported. However, based on the sandy nature of the surface soils mapped at the site and observed during field reconnaissance, the expansive potential of the soils at this site is considered low.

TABLE 10 – SUMMARY OF EXPANSIVE SOIL POTENTIAL AREAS TRAVERSED BY EACH SEGMENT[1]

SEGMENT/MILEPOST RANGE	SOIL DESCRIPTION	LINEAR EXTENSIBILITY PERCENT	EXPANSION POTENTIAL
D (34.7 -36.5)	Vertic Xerochrepts	7.5	High
K (14.3 – 14.6, 15.3 – 15.4)	Cropley-Urban land complex	7.5	High

Notes:

[1] Data from USDA(2007b, and 2008a, b, c and d).

Corrosive Soils

The Project study area is located in a geologic environment that could potentially contain soil conditions that are corrosive to concrete and buried metal structures. Corrosive soil conditions may exacerbate the corrosion hazard to concrete foundations, metal pipes and other buried concrete or metal improvements that are planned for the Project. Corrosivity of soils is generally a function of soil resistivity, presence of chlorides or sulfates, oxygen content, and pH. Typically, soil with low pH and high chloride/sulfate concentrations are more corrosive. High sulfate content soils are corrosive to concrete, and may limit concrete curing (and reduce its strength) or deteriorate concrete. Low pH and/or low resistivity soils could corrode buried metal structures.

In order to evaluate the erosion potential of the soils underlying the Project extents, data from the NRCS were evaluated. The NRCS data are available for only some of the soils traversed by the proposed Project, and some soils do not have reported information regarding their corrosive potential. Detailed assessment of the potential for corrosive soils in the Project study area would be evaluated on a site-specific basis during the design phase of the Project.

A summary of the corrosive potential of surface soils along the proposed corridor segments is presented in Table 11, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A. USDA data regarding the corrosive potential of surface soils at the proposed Haskell Canyon Switching Station have not been reported. The corrosive soil potential at the expanded Barren Ridge Switching Station has been categorized as low for concrete and moderate for steel.

TABLE 11 – SUMMARY OF CORROSIVE SOIL POTENTIAL AREAS TRAVERSED BY EACH SEGMENT[1]

SEGMENT	LENGTH OF SEGMENT (MILES)	AREAS WITH AVAILABLE DATA (MILES)	LOW CORROSIVE POTENTIAL (MILES)	MODERATE CORROSIVE POTENTIAL (MILES)	HIGH CORROSIVE POTENTIAL (MILES)
A	13.2	13.2	0.0	9.5	3.7
B	26.5	26.2	2.9	9.9	13.4
C	21.7	21.7	2.4	13.2	6.1
D	48.2	30.2	15.1	6.6	8.5
E	11.3	11.3	3.4	1.5	6.4
F	3.6	2.8	1.5	1.3	0.0
115th	4.8	4.7	1.8	2.8	0.0
G	21.2	6.5	2.6	3.6	0.3
2a	6.6	0.7	0.0	0.7	0.0
H	19.8	5.3	1.6	3.2	0.5
I	31.9	28.9	8.4	15.4	5.1
J	12.0	8.6	1.3	0.3	7.0
K	15.4	9.7	4.7	3.2	1.8

Notes:

[1] Data from USDA(2007b, and 2008a, b, c and d). When multiple soils occur in a single 1/10th mile, the higher potential corrosive value is considered.

Groundwater

Based on review of groundwater contour maps published in the CGS Seismic Hazard Evaluation reports, and available well data from the CDWR, groundwater is present underlying the proposed elements of the Project (CDWR, 2008). The historic high groundwater depths along the proposed segments of the Project are variable. In general, reported groundwater depths from available data in much of the Antelope Valley/Mojave Desert area are relatively deep and range from 138 to 336 feet below the ground surface. Some relatively shallow groundwater levels have been reported along the southern edge of the Antelope Valley and San Andreas Fault Rift Zone underlying Segments F, G and I. The data indicate that relatively shallow groundwater less than 50 feet deep is present in low-lying valley and other drainage areas in the southern portions of the Project study area. Segments D, G, I, J and K in this part of the Project study area are reportedly underlain by shallow groundwater. Data regarding groundwater levels at the proposed Haskell Canyon and expanded Barren Ridge switching stations are not available.

Data regarding areas of perched groundwater and perched groundwater depths are not readily available for the Project study area. Shallow perched groundwater can occur at variable locations due to seasonal variations, variations in ground surface topography, precipitation, irrigation practices, soil/rock types, groundwater pumping, and other factors, and may underlie the proposed Project segments.

A summary of approximate groundwater levels for the Project segments is presented in Table 12, and is listed for the corridor segments on a 1/10th mile basis in Appendix A.

TABLE 12 – SUMMARY OF GROUNDWATER LEVELS BY SEGMENT[1]

SEGMENT	RANGE OF APPROXIMATE GROUNDWATER DEPTHS FROM AVAILABLE DATA (FEET)
A	No data available
B	172 to 295
C	138
D	203 to 336 (Antelope Valley portion of segment) 10(milepost 34.8 to 35.0)
E	204 to 224
F	Less than 10 to 233
115th	167
G	Less than 10 to 184
2a	No data available.
H	No data available.
I	Less than 10 to 326
J	10
K	10 to 40

Notes:

[1] CDWR (2008); CGS Seismic Hazards Evaluation Reports.

Inundation from Dam Failure, Seiche or Tsunami

Based on review of the Safety Element chapters of the Los Angeles County (Los Angeles County, 1990) and Kern County General Plans (Kern County, 2007), portions of the Project study area could be affected by potential dam failures that could inundate the proposed Project corridors. The Los Angeles County General Plan indicates that areas susceptible to inundation from dam failure are present in the study area in the following locations in Los Angeles County:

- Bouquet Canyon and San Francisquito Canyon due to potential failure of the Bouquet Reservoir, which Segments D, G, H, J and K traverse.
- The south side of the Castaic Lake dam where Segments D and J traverse the inundation zone.
- The Antelope Acres area west of Lancaster due to potential failure of the Fairmont Reservoir, which Segments G and F traverse.
- The San Fernando area due to potential failure of the Van Norman reservoir at the south end of Segment K.

The General Plan for Kern County did not indicate areas of inundation from potential dam failure within the Kern County portion of the study area. The proposed Haskell Canyon and expanded Barren Ridge switching stations are not located in a dam failure inundation zone. A summary of potential dam inundation areas along the proposed corridor segments is presented in Table 13, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

TABLE 13 – SUMMARY OF DAM FAILURE INUNDATION AREAS

SEGMENT	LENGTH OF SEGMENT (MILES)	POTENTIAL DAM INUNDATION AREAS TRAVERSED (MILES)[1]
A	13.2	None
B	26.5	None
C	21.7	None
D	48.2	1.5
E	11.3	None
F	3.6	0.9
115th	4.8	None
G	21.2	1.4
2a	6.6	
H	19.8	0.3
I	31.9	0.8
J	12.0	1.5
K	15.4	1.0

Notes:

[1] Data from County of Los Angeles, 1990, Kern County, 2005; Kern County, 2007.

A seiche is the seismically induced sloshing of water in a large enclosed basin, such as a lake, reservoir, or bay. Bouquet Reservoir is in close proximity to Segment H, and Castaic Lake is in close proximity to Segments D and J in the Project area. The General Plans reviewed did not indicate the potential for inundation due to seiche from these water bodies.

Tsunamis are open-sea tidal waves generated by earthquakes. Tsunami damage is typically confined to low-lying coastal areas. Water surge caused by tsunamis is measured by distance of run-up on the shore. Due to the distance of the Project area from the Pacific coast, tsunamis would not affect the Project.

6.0 IMPACT ASSESSMENT - SEGMENTS

6.1 METHODOLOGY

This preliminary geotechnical evaluation for the proposed BRRTP has included review of soil, geologic and seismic background information, field reconnaissance, and assessment of potential impacts and mitigation recommendations to provide findings regarding the proposed corridors within the Project area. The proposed segments within the Project area were evaluated in regards to potential impacts to geologic resources and potential geologic and seismic hazards associated with implementation of the Project.

Geologic resources that may be affected by construction of the BRRTP include surficial soils that may be subject to erosion, and distinctive geologic features. Potential geologic hazards affecting the proposed Project include landslides or mudflows, soil erosion, subsidence, soil settlement, expansive soils, corrosive soils, groundwater, and inundation from dam failure or seiche. Potential seismic hazards that may affect the proposed BRRTP are surface fault rupture from active faults that cross the proposed corridors; high levels of ground shaking, liquefaction, and earthquake-induced landslides.

The assessment of potential impacts was performed by a study of the proposed segments relative to known geologic conditions, features and potential hazards. The segments were plotted on geologic maps, fault maps, Seismic Hazards maps, Earthquake Fault Zones maps and other geologic references to evaluate the potential for impacts. GIS data were utilized for evaluation of soils, geologic units, fault locations, Earthquake Fault Zone locations, anticipated ground shaking levels, liquefaction and earthquake-induced landslide zones (for some parts of the study area), potential soil erosion areas, expansive soils, and corrosive soils.

The potential impacts were evaluated using a 500-foot-wide "impact corridor." Geologic resources and potential hazards within the impact corridor were analyzed. An Impact Assessment Table was created to evaluate the proposed segments on a 1/10th mile basis to develop an assessment of initial impacts. Recommendations for mitigation have been developed for Project impacts and are presented in Section 6.5. Residual Project impacts based on implementation of mitigation recommendations are discussed in Section 7, and are also presented on the Impact Assessment Table included in Appendix A.

6.2 GEOLOGIC RESOURCE SENSITIVITY

The proposed Project has been evaluated with respect to its potential impacts on the geologic environment. Geologic resources that may be affected by construction of the BRRTP include surficial soils that may be subject to erosion, and distinctive geologic features. Assessment of the potential Project impacts on these features is based on the review of readily available USDA soil data and published geotechnical literature pertinent to the proposed Project, and limited field reconnaissance.

The following definitions have been provided regarding sensitivity criteria used for evaluation of geologic resources. Sensitivity is defined as a measure of probable adverse response of a resource to direct and indirect impacts associated with the construction, operation, and maintenance of Project components. Sensitivity levels for potential impacts to geologic resources are categorized as exclusion, high, moderate, or low, based upon the following general characteristics:

Exclusion: Areas where the siting of Project improvements is essentially precluded. This category includes areas where there would be unacceptable geologic impacts due to the construction or operation of a transmission line or switching station.

High Avoidance: Areas have high sensitivity due to substantial geologic impacts due to construction and operation of a transmission line or switching station. For the purposes of this study, areas designated as high sensitivity are considered least desirable and should be avoided, if possible, or mitigation implemented to reduce the adverse impacts.

Moderate Avoidance: Areas have moderate sensitivity due to limited geologic impacts due to construction and operation of a transmission line or switching station. For the purposes of this study, areas designated as moderate sensitivity are not considered highly desirable, but may be used with mitigation of adverse impacts.

Low Avoidance or Opportunities: Areas have low sensitivity where there are no or slight geologic impacts due to construction and operation of a transmission line or switching station. For the purposes of this study, areas designated as low sensitivity are more desirable for the siting of Project components.

TABLE 14 – SENSITIVITY RATINGS FOR GEOLOGIC RESOURCES

RESOURCE COMPONENT	SENSITIVITY RATING				RATIONALE
	EXCLUSION	HIGH	MODERATE	LOW	
Soils with Very Severe to Severe Erosion Potential		X			High potential for significant impacts from soil loss due to erosion.
Soils with Moderate Erosion Potential			X		Moderate potential for significant impacts from soil loss due to erosion.
Soils with Slight Erosion Potential				X	Low potential for significant impacts from soil loss due to erosion.
Geologic Unit Contains Distinctive Geologic Features (Prominent or Unique Outcrops, Scenic Formations, San Andreas Fault Zone, White Tuff Beds)		X			High potential for impacts to distinctive geologic features.
Geologic Unit May Contain Distinctive Geologic Features (Significant Marker Beds, Scenic Formations)			X		Moderate potential for impacts to distinctive geologic features.
Geologic Unit (Alluvium or soil-covered areas) Does Not Contain Distinctive Geologic Features				X	Low potential for impacts to distinctive geologic features.

Notes: Sensitivity criteria provided by Power Engineers.

6.3 POTENTIAL GEOLOGIC AND SEISMIC HAZARDS

The impacts of potential geologic and seismic hazards that may affect the proposed BRRTP have been evaluated. Assessment of these potential impacts is based on geologic and seismic review of readily available published geotechnical literature and data pertinent to the proposed Project, and limited field reconnaissance.

Potential seismic hazards that may affect the proposed BRRTP involve surface fault rupture from active faults that cross the proposed corridors; high levels of ground shaking, liquefaction, and earthquake-induced landslides. Potential geologic hazards that may affect the proposed Project include landslides or mudflows, erosion, subsidence, soil settlement, expansive soils, corrosive soils, groundwater, and inundation from dam failure or seiche.

6.4 IMPACT LEVELS

Table 15 presents the impact potential, as defined by CEQA, associated with each of the geologic conditions discussed in the following sections, and the corresponding impact level utilized in this study for impact assessment. According to Appendix G of the CEQA guidelines (CERES, 2005b), a project is considered to have a geologic impact if its implementation would result in or expose people/structures to potential substantial adverse effects, including the risk of loss, injury, or death related to hazards expressing one or more of the geologic conditions presented in this evaluation.

TABLE 15 – IMPACT LEVELS

IMPACT LEVEL	IMPACT POTENTIAL[1]
High	Potentially significant impact.
Moderate	Less than significant with mitigation incorporation.
Low	Less than significant impact.
No	No impact.

Note:

[1] Reference: CERES, 2005b, Appendix G, Environmental Checklist Form, Final Text, dated October 26

6.5 MITIGATION RECOMMENDATIONS

The potential geologic and seismic impacts that may affect the BRRTP may be mitigated by employing sound engineering practice in the planning, design and construction of the new improvements proposed for the Project. This practice includes performance of the following general and specific techniques discussed below prior to the design and construction of the BRRTP.

6.5.1. Soil Loss/Soil Erosion

Construction for the proposed Project is anticipated to create the potential for soil erosion during excavation, grading, and trenching activities for access roads, tower sites, pulling and tensioning sites and the construction of switching stations. However, with the implementation of prudent site practices during construction, water- and wind-related soil erosion can be limited and managed within construction site boundaries. Examples of these procedures would include surface drainage measures for erosion due to water, such as the use of erosion prevention mats or geofabrics, silt fencing, sandbags and plastic sheeting, and temporary drainage devices. Positive surface drainage should be accommodated at Project construction sites to allow surface runoff to flow away from site improvements, slope faces or areas susceptible to erosion. To mitigate wind-related erosion, wetting of soil surfaces and/or covering exposed ground areas and soil stockpiles could be considered during construction operations, as appropriate. The use of tackifiers may be considered to reduce the potential for water- and wind-related soil erosion.

Where deemed appropriate for areas of significant concern, limited access areas, or areas of very steep terrain, other practices could be considered to mitigate erosion. These practices may include avoiding these areas, or utilizing construction practices to reduce impacts. Helicopter-access could be utilized where warranted during construction in these areas to reduce ground disturbance by eliminating the need for access road construction. Using specialty foundations systems for towers, such as micropiles or hand-excavated foundations, could be considered to reduce the ground impact related to foundation construction. The need for these practices would be considered during the design phase of the Project based on Project improvement site locations. As needed, a Storm Water Pollution Prevention Plan (SWPPP) could be developed for construction sites that would include the use of Best Management Practices (BMPs). The SWPPP would also include specific statements about the required effectiveness of the BMPs, as well as plans for routine inspection and maintenance to ensure that the BMPs continue to function effectively.

During long-term operation of the transmission line improvements, soil erosion can be mitigated through prudent site design and maintenance practices. Design procedures can be performed to reduce soil erosion such as appropriate surface drainage design of roadways and tower pad areas to provide for positive surface runoff. Design would address reducing concentrated run-off conditions that could cause erosion rilling and affect the stability of Project improvements. The use of erosion control fabrics and roadway drainage devices can be designed and maintained to reduce erosion processes.

6.5.2. Distinctive Geologic Features

Distinctive geologic features are present in the Project study area, and the potential impacts to these features would be specifically evaluated during Project design. During the design phase, preliminary Project plans would be reviewed and the locations of proposed access roads, tower sites and pulling and tensioning sites would be field checked for impacts to distinctive geologic features.

Prominent rock features are, by nature, typically harder than the surrounding materials. They are, therefore, more difficult to excavate and present more difficulty in grading of roads, tower sites and pulling and tensioning sites. Project designers and contractors may prefer to avoid these features for ease of construction and in efforts to reduce Project costs. Measures to mitigate the impacts to distinctive geologic features include avoiding the features. Design considerations would include siting of towers, roads and pulling and tensioning sites away from the geologic feature. Design plans and site grading could be achieved to facilitate the highly sensitive landforms and surrounding gradients in efforts to reduce Project costs and thus avoid more highly distinctive geologic features.

6.5.3. Surface Rupture

To assess the potential fault-rupture hazard for the proposed Project components related to active faults, evaluation may include review of geologic maps showing the locations of active faults relative to Project improvements. Where appropriate in close proximity to active faults, surface reconnaissance to map the locations of active faults and/or subsurface evaluation may be performed. Evaluation of potential fault-rupture hazard to Project improvements would be performed prior to design and construction so that, in the event a fault-rupture hazard exists, mitigation techniques can be implemented. Recommendations for mitigation of potential fault rupture hazard would typically include locating transmission system improvements away from the trace of an active fault, designing the conductor system for an acceptable amount of movement, or implementing systems to maintain safety and allow for displacement that could be repaired to make the system operational.

Surface reconnaissance to evaluate potential surface fault rupture may include checking of geologic maps and visual observation of the earth units and geomorphology in order to locate active faults relative to the alignment. Ground features that may indicate the location of active faults may be concealed by natural soils, fill soils or manmade improvements, and surface reconnaissance may not be adequate to locate active faults with potential for surface rupture. Consequently, subsurface exploration may be appropriate to evaluate fault locations and conditions. Subsurface evaluation might include the excavation and detailed logging of exploratory trenches and/or borings, geophysical studies such as high resolution seismic reflection, seismic refraction, ground penetrating radar, gravity and/or magnetic profiling or other applicable methods.

Transmission systems throughout California cross active faults. With the prevalence of active faulting in this seismically active region, the crossing of active faults is unavoidable. In this regard, mitigation of the potential surface fault rupture hazard in some areas of the segment may not involve avoiding the fault, but would involve designing the system for the anticipated displacement to reduce the damage while providing for the safety of the public.

Mitigation for potential fault-rupture hazard could include various techniques. Foundations for towers or other structures can be located away from the fault trace to avoid the fault. Locating improvements a sufficient distance from active faults would limit damage to the system as long as the fault ruptures along the identified surface and does not rupture along a new surface. Planning for the anticipated displacement by the use of additional slack in the conductor, or placing “dead-end” tower structures on both sides of a fault trace may reduce damage to the system and non-operational time.

6.5.4. Seismic Ground Shaking

Site-specific evaluation of the potential ground-shaking hazard for the proposed Project components would be performed prior to design and construction so that appropriate structural design and mitigation techniques can be implemented. Typically, this evaluation would involve the use of geotechnical software programs utilizing site latitudinal and longitudinal coordinates and general site geologic information to evaluate the potential levels of ground shaking at specific locations. Where deemed appropriate during Project design, site-specific geotechnical evaluations to assess the subsurface characteristics of the on-site earth materials with regard to ground shaking could be performed. Subsurface data could be obtained through exploratory excavations and laboratory testing of soils.

Mitigation of the potential impacts of seismic ground shaking can be achieved through Project design. During the design phase, site-specific geotechnical evaluations would be performed to analyze the site-specific ground motion anticipated for the transmission line improvements. Site-specific evaluation of the potential ground shaking hazard would involve evaluation to develop seismic design parameters for use by the Project structural engineer. Structural elements of the transmission line system can then be designed to resist or accommodate appropriate site-specific ground motions and to conform to the current seismic design standards.

6.5.5. Liquefaction

Liquefaction would typically be a potential hazard in parts of the Project area where liquefaction-prone conditions are present (loose granular soils and shallow groundwater) and include stream, valley and canyon bottoms within the study corridors. In these areas of the proposed Project, foundations for towers or other structures can be located to avoid potential liquefaction areas and mapped liquefaction zones, such as moving tower location upslope from a valley bottom.

To evaluate the potential liquefaction hazard for the proposed Project components in areas of potential liquefaction concern, subsurface evaluation could be performed. Site-specific evaluation of the potential liquefaction hazard would be performed prior to design and construction so that, in the event a liquefaction hazard exists, appropriate structural design and mitigation techniques can be implemented. Site-specific geotechnical evaluations to assess the liquefaction and dynamic settlement characteristics of the on-site soils would include drilling of exploratory borings, evaluation of groundwater depths, and laboratory testing of soils.

Mitigation for construction in liquefaction zones may include in-situ ground modification, removal of liquefiable layers and replacement with compacted fill, or support of Project improvements with piles at depths designed specifically for liquefaction. Pile foundations can be designed for liquefaction hazard by supporting the piles in dense soil or bedrock below the liquefiable zone or other appropriate methods as evaluated during the site-specific evaluation. Additional recommendations for mitigation of potential liquefaction may include densification by installation of stone columns, vibration, deep dynamic compaction, and/or compaction grouting.

6.5.6. Landslides

To evaluate the potential for landslides, surficial slope failures and/or mudflows to affect the proposed Project components, evaluation may include review of geologic maps showing the locations of landslides and potential earthquake-induced landslide zones relative to these Project components. Where appropriate in close proximity to potential landslide areas, surface reconnaissance to map the locations of landslides and/or subsurface evaluation could be performed. Evaluation of the landslide and surficial slope failure hazard would be performed prior to design and construction so that, in the event the hazard exists, mitigation techniques can be implemented.

Surface reconnaissance to evaluate the potential for landslides and surficial slope failures would be performed in the design phase and may include checking of geologic maps and visual observation of the conditions of slopes and site geomorphology in order to locate landslides or potential landslide areas relative to proposed tower locations and the Haskell Canyon site. Subsurface exploration may be appropriate to evaluate the potential for landslides and surficial slope failures. Subsurface evaluation might include the excavation and detailed logging of exploratory trenches, test pits and/or borings. Slope stability computer analyses may be performed to address the stability of slopes in the Project areas.

To mitigate the potential landslide hazard in some areas of the proposed Project, transmission towers can be located away from a landslide, and avoid it by spanning across, above or below the landslide feature. Access roads can be designed and constructed to avoid landslides or reduce impacts due to landslides through grading techniques. Where deemed appropriate for areas of significant concern, helicopter-based construction techniques may be implemented to avoid building access roads across landslides or landslide-prone terrain. Measures to mitigate potentially unstable slope conditions and mitigate the potential for landslides and surficial slope failures include: excavating potentially unstable material resulting in a flatter more stable slope configuration; reduction of landslide driving forces by removal of earth materials at the top of the landslide; construction of buttress and/or stabilization fills; construction of retaining walls, installation of rock bolts on the face of the slope, or installation of protective wire mesh on the slope face; and/or the construction of debris impact walls at the toe of the slope to contain rock fall debris.

6.5.7. Subsidence

The background review did not indicate that subsidence has been recently reported in the Project area. Therefore, potential subsidence is considered to have a low impact and recommendations for mitigation are not provided.

6.5.8. Soil Settlement

To evaluate the potential for settlement to affect the proposed Project components, surface reconnaissance and subsurface evaluation could be performed. During the design phase of the Project, site-specific geotechnical evaluations would be performed to assess the settlement potential of the on-site natural soils and undocumented fill. This may include detailed surface reconnaissance to evaluate site conditions, and drilling of exploratory borings and laboratory testing of soils, where warranted, to evaluate site conditions. Evaluation of the potential soil settlement hazard would be performed prior to design and construction so that, in the event the hazard exists, mitigation techniques can be implemented.

In some areas of the proposed Project, foundations for towers or other structures and roadways can be located to avoid potential areas of settlement. Examples of possible mitigation for soils with potential for settlement include removal of the compressible/collapsible soil layers and replacement with compacted fill; surcharging to induce settlement prior to construction of improvements; allowing for a settlement period after or during construction of new fills; and specialized foundation design including the use of deep foundation systems to support structures. Varieties of in-situ soil improvement techniques are also available, such as dynamic compaction (heavy tamping) or compaction grouting.

6.5.9. Expansive Soils

To evaluate the potential for expansive soils to affect the proposed Project components, subsurface evaluation including laboratory testing could be performed. Site-specific, subsurface evaluation could be conducted during the design phase of the Project to evaluate the potential extent of expansive soils along the proposed segments. Where expansive soil conditions are found to occur and are considered detrimental to proposed improvements, mitigation techniques can be implemented. Evaluation of the potential expansive soils hazard would be performed prior to design and construction so that, in the event the hazard exists, mitigation techniques can be implemented, including avoiding areas of expansive soils. To avoid site-specific subsurface evaluation, design measures to accommodate expansive soil activity can be included in the initial design for the proposed Project improvements.

Mitigation for expansive soils would typically include techniques such as overexcavation and replacement with non-expansive soil, chemical treatment (e.g., lime or cement), moisture control, and/or specific structural design for expansive soil conditions developed during design of the Project.

6.5.10. Corrosive Soils

To evaluate the potential for corrosive soils to affect the proposed Project components, subsurface evaluation including laboratory testing could be performed. Evaluation of the corrosive soil potential can be accomplished by testing and analysis of soils at foundation design depths. The laboratory tests conducted on the soils prior to construction and improvement plan preparation would include corrosivity tests to evaluate the corrosivity of the subsurface soils. Review of these data by a corrosion engineer would result in corrosion protection measures suitable to the Project elements. Evaluation of the potential corrosive soils hazard would be performed prior to design and construction so that, in the event the hazard exists, mitigation techniques can be implemented, including avoiding areas of corrosive soils. To avoid site-specific subsurface evaluation, corrosion protection measures can be included in the initial design for the proposed Project improvements.

Mitigation of corrosive soil conditions may involve the use of concrete resistant to sulfate exposure. Corrosion protection for metals may be needed for underground foundations or structures in areas where corrosive groundwater or soil could potentially cause deterioration. Typical mitigation techniques include epoxy and metallic protective coatings, the use of alternative (corrosion resistant) materials, and selection of the appropriate type of cement and water/cement ratio. Specific measures to mitigate the potential effects of corrosive soils would be developed in the design phase.

6.5.11. Groundwater

To evaluate the potential for groundwater that may affect construction of the proposed Project components, subsurface evaluation could be performed. Evaluation of the potential shallow groundwater hazard would be performed prior to design and construction so that, in the event the hazard exists, mitigation techniques can be implemented, including avoiding areas of shallow groundwater or preparation for the anticipated groundwater during construction. Site-specific geotechnical evaluations to assess the groundwater characteristics may include review of available groundwater data, drilling of exploratory borings, evaluation of groundwater depths, and possible installation of groundwater monitoring wells, where needed.

Measures to mitigate potential shallow groundwater conditions would include: shoring/casing of excavations below the groundwater table to prevent inundation of the excavated area; pumping groundwater from excavations to keep levels below a specified depth; using dewatering wells to pump groundwater out of the ground and lower the groundwater table at specified locations; and, where needed, utilizing more advanced, and costly techniques to manage groundwater, such as the use of subsurface grout curtains or soil/cement walls. Measures to mitigate the potential impacts of excavation spoils that are saturated due to groundwater would include sandbags or berms, or the use of bins or drums to contain the excavation materials and water and reduce impacts to surface soils and surface water quality. Where deemed appropriate for areas of significant concern, the use of micropile foundations for towers could be utilized to reduce construction impacts related to drilling of larger excavations for foundations, which may be prone to impacts due to shallow groundwater.

6.5.12. Inundation from Dam Failure, Seiche or Tsunami

To evaluate the potential for dam inundation or seiche to affect the proposed Project components, review of dam inundation maps and detailed hydrologic evaluation could be performed to assess the risks and potential effects of inundation to particular Project areas. Evaluation of potential dam inundation or seiche hazards at site-specific locations would be performed prior to design and construction so that, in the event of inundation, measures could be in place to mitigate the effects.

Measures to mitigate the potential inundation due to dam failure or seiche would include raising the elevation of the proposed transmission tower locations to keep them elevated above the potential inundation level. These types of inundation effects are anticipated to be temporary, and may necessitate minor maintenance in the affected segments to make the system operational.

Since the Project area is not considered susceptible to tsunami inundation, the proposed Project would not result in impacts related to tsunamis, and recommendations for mitigation are not provided.

7.0 IMPACT RESULTS

The initial impact results for each component of the Project are presented in the following sections. These Project components include: 1) construction of the new 230 kV transmission line from Barren Ridge to Haskell Canyon; 2) the new 230 kV circuit placed on existing towers from Haskell Canyon to Castaic; 3) the 230 kV reconductoring placed on existing towers from Barren Ridge to Rinaldi; 4) construction of the new Haskell Canyon Switching Station; and 5) expansion of the Barren Ridge Switching Station.

Assessment of the results for the proposed new 230 kV transmission line is presented by impact type in the following sections. Summary tables are provided in the impact type sections in order to compare the level of impact of the proposed routing segments with each other. Since the components are evaluated as segments, assessment of the impacts of the new 230 kV circuit from Haskell Canyon to Castaic (evaluated as Segment J) and the 230 kV reconductoring from Barren Ridge to Rinaldi (evaluated as Segments A, B, G and K) is also presented in Section 7.1.

7.1 NEW 230 KV TRANSMISSION LINE - SEGMENTS

The initial impact results in this section of the report are presented in order to evaluate the proposed construction of the new 230kv transmission line. A summary of the relative geologic impacts for each proposed segment of the transmission line Project is summarized below in Table 16. Detailed discussion and presentation of the individual impacts follows.

This preliminary geotechnical evaluation has considered assessment of the potential geologic resources in the affected environment that may be impacted by construction of the proposed BRRTP. Inversely, the preliminary evaluation has also considered the potential geologic and seismic hazards in the affected environment that may have impacts on development of the proposed Project. The potential geologic resources in the environment that may be impacted by the Project include highly erosion-sensitive soils and distinctive geologic features. The potential geologic and seismic hazards that may have an impact to the Project include surface fault rupture, seismic ground shaking, liquefaction, landslides, erosion, settlement, expansive soils, corrosive soils, groundwater and inundation from potential dam failure. These potential impacts may affect individual components of the Project, including transmission towers, access roads and/or the switching stations.

During the design phase when the Project components are being sited, the potential Project impacts would be evaluated through data review, geologic reconnaissance and subsurface exploration, as appropriate. The results of the site-specific evaluations would be incorporated into the design of the Project components. Through this process, the highly sensitive geologic resources that could be affected would be located and mitigation would be implemented to reduce the impacts to low levels. The potential geologic and seismic hazards would be considered relative to the construction of Project components, and mitigation techniques would be developed to reduce the impacts to low levels that would be appropriate for design. With the implementation of the appropriate mitigations, the initial impacts to geologic resources and impacts related to potential seismic and geologic hazards can be reduced to low residual levels.

THIS PAGE INTENTIONALLY LEFT BLANK

7.1.1. Soils

This potential geologic impact refers to the proposed Project's potential to cause erosion loss of surface soils, and impacts to potentially sensitive soils. Based on NRCS soil data, soils with varying degrees of erosion potential are located along the proposed Project segments and at the switching station sites. Potential areas of erosion for the Project have been categorized as slight, moderate, severe and very severe (USDA, 2008d). These erosion potential levels correspond to low, moderate and high sensitivity ratings, respectively. If implementation of the proposed Project components would cause significant erosion and loss of high-sensitivity-rating surface soils, then erosion would have a high impact on soil resources. Significant erosion and loss of moderate-sensitivity-rating surface soils would have a moderate impact on the soil resources. Significant erosion and loss of low-sensitivity-rating surface soils would have a low impact on the soil resources.

A summary of sensitivity levels/potential initial impacts to soils is provided below in Table 17. A summary of sensitivity ratings for soils underlying the proposed Project segments is presented on a 1/10th mile basis in the USDA Soils table in Appendix B.

Future construction activities for the Project would result in ground surface disruption during excavation, grading, and trenching that would create the potential for erosion to occur and impact sensitive soils. However, the erosion potential during construction can be mitigated with prudent site management practices during construction (specified in the SWPPP). Following development of site improvements, erosion can be mitigated by long-term erosion management practices incorporated into the design and maintenance of the Project. With incorporation of mitigation techniques, future site erosion and impacts to sensitive soils can be reduced. Potential soil erosion related to the Project development is considered to have a low residual impact with mitigation incorporation.

Notes:
[1] Data from USDA(2008d); Data for some portions of Segment K are not available.

7.1.2. Distinctive Geologic Features

This potential geologic impact refers to the proposed Project's potential to cover or modify distinctive, prominent geologic features with potentially high sensitivity rating, which could occur during grading or excavation activities related to Project construction. Distinctive geologic features can include unique marker beds, scenic rock formations or significant outcrops. Based on background review and limited field reconnaissance, there are distinctive geologic features that are present in some of the rock formations in the Project study area.

Geologic features traversed by the proposed segments in the BRRTP study area that are considered distinctive, and would have a high sensitivity rating, include the white tuff (volcanic ash) marker beds that are mapped and outcrop in the Bouquet Canyon/Vasquez Canyon area traversed by Segment I.

Rock formations in the Project study area are present in the southern part of Segment D, and in Segments G, 2a, H, I, J, and portions of Segment K. The majority of these geologic formations contains more common rock outcrops, exposed road cuts and soil-covered areas, and is not considered highly distinctive. However, distinctive geologic features may be present in limited areas of some rock formations in the Project study area not indicated on geologic maps or observed during field reconnaissance. Therefore, these rock formation units have been assigned a moderate sensitivity rating.

The Mojave Desert and Antelope Valley portions of the Project, and other low-lying valley areas with alluvium and soil cover, do not comprise rock formations at the ground surface and do not contain distinctive geologic features. These areas have been assigned a low sensitivity rating.

A summary of sensitivity ratings and potential initial impact levels due to distinctive geologic features is provided below in Table 18, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

The construction of the transmission Project would result in grading and excavation activities for tower and access road construction in areas of rock formations. Grading of rock formations can often be difficult, and designers and contractors typically prefer to avoid this more costly operation. Design plans and site grading could be achieved to facilitate the landforms and surrounding gradients as much as possible in efforts to reduce Project costs and thus avoid more distinctive geologic features. Therefore, the impacts related to the alteration or modification of distinctive geologic features would be reduced. Assessment of the potential for impacts to distinctive geologic features would be evaluated during the design phase of the Project when plans are being developed, and mitigation techniques would be developed, as appropriate, to reduce the impacts to distinctive geologic features to low levels. Therefore, the potential residual impacts due to distinctive geologic features are considered low with anticipated mitigation.

TABLE 18 – SUMMARY OF POTENTIAL INITIAL IMPACTS TO DISTINCTIVE GEOLOGIC FEATURES[1]

SEGMENT	LENGTH OF SEGMENT (MILES)	LOW IMPACT LEVEL AREAS TRAVERSED (MILES)	MODERATE IMPACT LEVEL AREAS TRAVERSED (MILES)	HIGH IMPACT LEVEL AREAS TRAVERSED (MILES)

Notes:

[1] Dibblee, 1997c, 1997f, 2002b; field observations.

7.1.3. Surface Rupture

The high probability for surface fault rupture within the Project study area is along active faults, particularly along the active faults designated as Earthquake Fault Zones. There is a high impact associated with construction of Project improvements across the traces of active faults and areas within the Earthquake Fault Zones. Other potentially active and inactive faults are located in the study area and underlie some of the proposed segments. Due to the less active nature of these types of faults, they have been assigned a moderate impact to the Project. A summary of potential initial impact levels due to faults crossed by the proposed Project segments is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A. A summary of potential initial impact levels due to earthquake fault zones is provided below in Table 19, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

Development within Earthquake Fault Zones would need further evaluation to address the potential for fault rupture. The initial impacts related to surface fault rupture are high. Damage could occur to the proposed transmission line improvements due to fault rupture if those elements are constructed across the fault rupture surface. Damages may include offset/damage to towers or roadways at portions of the segments crossing the fault rupture; damage to structural elements of the transmission towers that are placed across the fault rupture; or damage to facilities built across the fault rupture. Assessment of the surface fault rupture potential would be evaluated prior to design and construction of Project improvements and incorporated into the design, as appropriate, to reduce the impacts related to surface rupture to low levels. Therefore, the potential residual impacts due to surface fault rupture are considered to be low with incorporation of mitigation techniques such as fault trenching to check for fault traces and re-locating towers to avoid fault traces, as appropriate.

TABLE 19 – SUMMARY OF POTENTIAL INITIAL IMPACTS DUE TO EARTHQUAKE FAULT ZONES

7.1.4. Seismic Ground Shaking

The seismic hazard likely to impact the Project area is ground shaking during an earthquake on one of the nearby or distant active faults. The level of ground shaking at a given location depends on many factors, including the size and type of earthquake, distance from the earthquake, and subsurface geologic conditions. The size and type of construction also affects how particular structures perform during ground shaking. Ground shaking could cause detrimental damage to Project improvements if the appropriate design for the anticipated level of shaking is not considered. Damages due to ground shaking could include misaligned towers and other structural elements, and cracks in concrete foundations, walls and structures such as the proposed Haskell Canyon Switching Station.

Based on the review of seismic data, peak horizontal ground accelerations in the range of 0.25 g to 0.80 g are anticipated to affect the Project study area. Peak horizontal ground accelerations less than 0.30 g are considered to have a low initial impact; peak horizontal ground accelerations in the range of 0.30g to 0.40g are considered to have a moderate initial impact; and peak horizontal ground accelerations in the range of 0.50g to 0.80g are considered to have a high initial impact. A summary of potential initial impact levels due to ground shaking is provided below in Table 20, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

Assessment of the ground shaking potential would be evaluated prior to design and construction of Project improvements and incorporated into the design, as appropriate, to reduce the impacts related to seismic ground shaking to low levels. Therefore, the potential residual impacts due to ground shaking are considered to be low with incorporation of mitigation techniques such as designing the structural elements of the transmission line system to resist or accommodate appropriate site-specific ground motions.

TABLE 20 – SUMMARY OF POTENTIAL INITIAL IMPACTS DUE TO GROUND SHAKING

7.1.5. Liquefaction

Review of the state maps and data indicate that portions of some segments of the Project are underlain by potential liquefaction zones. Liquefaction could cause damage to proposed Project improvements without appropriate consideration during design, and areas that are mapped as liquefaction zones have a potentially high impact on the Project. The potential damaging effects of liquefaction include differential settlement, loss of ground support for foundations, ground cracking, heaving and cracking of slabs due to sand boiling, buckling of deep foundations due to liquefaction-induced ground settlement, and lateral spreading along embankments and natural slopes along drainages. A summary of potential initial impact levels due to liquefaction hazard zones is provided below in Table 21, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

The State of California Seismic Hazards Mapping Program produces maps identifying potential liquefaction hazard zones, and has produced these maps for some quadrangles within the Project study area. Many quadrangles within the study area have not been mapped by the State. Potential liquefaction hazard zones underlying proposed route segments in the study area that have been mapped by the State are included in the evaluation, where available. In order to make a comparison of the proposed route segments for areas of available data and areas that do not have available data, a ratio of the miles of liquefaction zones to the miles of available data for each segment is presented below in Table 21.

According to Seismic Hazards Zones Maps published by the State of California, portions of the Project are mapped within areas that are considered susceptible to liquefaction. In addition, areas of the Project not mapped in a Seismic Hazards Zone may have potential for liquefaction. Assessment of the liquefaction potential would be evaluated prior to design and construction of Project improvements and incorporated into the design, as appropriate, to reduce the impacts related to liquefaction to low levels. Therefore, the potential residual impacts due to liquefaction are considered to be low with incorporation of mitigation techniques such as avoiding the liquefaction zone by moving tower locations upslope from valley bottoms, in-situ ground modification, or supporting towers with piles at depths designed specifically for liquefaction.

TABLE 21 – SUMMARY OF POTENTIAL INITIAL IMPACTS DUE TO LIQUEFACTION HAZARD ZONES

SEGMENT	LENGTH OF SEGMENT (MILES)	AVAILABLE DATA (MILES)	HIGH IMPACT LEVEL LIQUEFACTION HAZARD ZONES TRAVERSED (MILES)[1]	RATIO OF LIQUEFACTION ZONES TO AVAILABLE DATA

Notes:

[1] Data from California Geological Survey Seismic Hazards Mapping Program for available quadrangles in the study area (some quadrangles and data not available).

7.1.6. Landslides

The review of referenced geologic maps and field reconnaissance indicates that existing mapped landslides are present along some proposed segments of the Project. Additionally, some steep areas of the Project have been designated as potential Earthquake-Induced Landslide Hazard Zones by the State of California. Some mapped landslides and potential earthquake-induced landslide zones occur at the same location within the Project study corridors. Both the mapped landslide areas and potential Earthquake-Induced Landslide Hazard Zones are considered to have a potentially high initial impact on the Project, if improvements are constructed on the landslide areas. A summary of potential initial impact levels due to mapped landslides is provided below in Table 22, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A. A summary of potential initial impact levels due to earthquake-induced landslide hazard zones is provided below in Table 23, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

Geologic maps utilized to evaluate existing landslides in the Project study area were available for the steep mountainous areas within the ANF and surrounding mountainous areas where landslides may occur, generally along Segments D, G, 2a, H and I. In order to make a comparison of the proposed route segments, a ratio of the miles of mapped landslides to the miles of available data for each segment is included in Table 22. The State of California Seismic Hazards Mapping Program produces maps identifying potential earthquake-induced landslide hazard zones, and has produced these maps for some quadrangles within the Project study area. Many quadrangles within the study area have not been mapped by the State. Potential earthquake-induced landslide hazard zones underlying proposed route segments in the study area that have been mapped by the State are included in the evaluation, where available. In order to make a comparison of the proposed route segments for areas of available data and areas that do not have available data, a ratio of the miles of earthquake-induced landslide zones to the miles of available data for each segment is included in Table 23.

Portions of the Project located in areas of steep terrain (including mapped landslide areas and areas that do not have mapped landslides) may have potential landslide hazard. Slope areas within the study area, including constructed cut slopes, fill slopes, and natural slopes, could potentially be affected by landsliding or other steep slope problems. Slopes may have potential for surficial slope failures and/or mudflows during rainfall. Slopes cut in bedrock may be subject to rock fall, rock slides, or other rock slope failures where discontinuities, such as joints and fractures, or weathered rock are encountered. Landslides and surficial slope failures (mudflows), if not mitigated, can cause damage to slopes, embankments, roadways, transmission towers, foundations and other structures that are founded on or affected by the landslide. Due to the relatively flat-lying nature of some segments of the Project in the Antelope Valley, Mojave Desert, and valleys, landslide hazards are considered low in those areas of gentle slopes.

Assessment of the landslide and mudflow potential in areas of Project improvements would be evaluated prior to design and construction improvements and incorporated into the design, as appropriate, to reduce the impacts related to landslides to low levels. Therefore, the potential residual impacts due to landslides are considered to be low with incorporation of mitigation techniques such as avoiding landslides by moving tower locations, excavating potentially unstable earth materials, slope stabilization methods, or building of retaining structures.

TABLE 22 – SUMMARY OF POTENTIAL INITIAL IMPACTS DUE TO MAPPED LANDSLIDES

7.1.7. Soil Erosion

Based on NRCS soil data, surface soils with erosion potential ranging from slight to moderate to severe and very severe have been mapped in the Project study area. In addition to the loss of surface soils as a geologic resource, erosion of soils and earth materials can cause damage to Project improvements such as tower foundations, switching station facilities, access roads, and manufactured slopes. Erosion can potentially result in the loss of support or undermining of these Project improvements. Construction of Project improvements on soils with a severe to very severe erosion potential would have a high initial impact to Project improvements. Soils with a moderate erosion potential would have a moderate initial impact, and soils with a slight erosion potential would have a low initial impact. A summary of potential initial impact levels due to soil erosion is provided below in Table 24, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A. The soil erosion potential at the proposed Haskell Canyon Switching Station has been categorized as severe, and the impact of erosion at this site is considered high. The soil erosion potential at the expanded Barren Ridge Switching Station has been categorized as slight, and the impact at this site is considered low.

Future construction activities for the Project would result in ground surface disruption during excavation, grading, and trenching that would create the potential for erosion to occur. However, the erosion potential during construction can be mitigated with prudent site management practices during construction. Following development of site improvements, erosion can be mitigated by long-term erosion management practices incorporated into the design and maintenance of the Project. With incorporation of mitigation techniques, future site erosion can be reduced. Potential soil erosion related to the Project development is considered to have a low residual impact with mitigation incorporation.

TABLE 24 – SUMMARY OF POTENTIAL INITIAL IMPACTS DUE TO SOIL EROSION[1]

SEGMENT	LENGTH OF SEGMENT (MILES)	LOW IMPACT LEVEL AREAS TRAVERSED (MILES)	MODERATE IMPACT LEVEL AREAS TRAVERSED (MILES)	HIGH IMPACT LEVEL AREAS TRAVERSED (MILES)
A	13.2	13.2	0.0	0.0
B	26.5	25.9	0.0	0.6
C	21.7	21.5	0.2	0.0
D	48.2	17.5	4.7	26.0

2a	6.6	0.0	0.7	5.8
H	19.8	2.2	1.6	16.0
I	31.9	5.3	7.0	19.6
J	12.0	0.3	0.4	11.6
K	15.4	0.9	0.4	8.8

Notes:

[1] Data from USDA (2008d).

Data for some portions of Segment K are not available.

7.1.8. Subsidence

The background review did not indicate that subsidence has been recently reported in the Project area. No subsidence-induced ground cracks were observed crossing the proposed Project segments or switching station sites during field reconnaissance. Damage to existing transmission improvements in these areas was not reported. However, the geologic components for subsidence are present in some parts of the Project study area (valley areas), and subsidence is considered to have a potentially low initial impact.

7.1.9. Settlement

Compressible natural soils and undocumented fills pose the risk of adverse settlement under static loads imposed by new embankment fills, roadway fills, tower foundations and associated structures. Differential settlement of soils can cause damage to Project improvements including concrete structures and foundations, retaining walls, associated switching stations and maintenance structures and pavements. Constructing Project improvements on soils known to have a potential for settlement would have a high initial impact to the Project.

Since the Project would involve construction of new improvements that would be loaded upon the existing soils, potential settlement and/or collapsible soils should be a consideration in design and construction of Project improvements. Assessment of the potential for soils prone to settlement would be evaluated prior to design and construction of Project improvements and mitigation techniques would be developed, as appropriate, to reduce the impacts related to settlement to low levels. Therefore, the potential residual impacts due to soil settlement are considered low with incorporation of mitigation techniques such as avoiding areas prone to settlement, removal and recompaction of compressible soils, specialized foundation design including the use of deep foundation systems to support structures, and in-situ ground modification.

7.1.10. Expansive Soils

Based on limited NRCS soil data, potentially expansive soils may be present along portions of Segments D and K of the proposed Project. Expansive soils may also be present in areas of the Project not indicated by the limited NRCS soil data.

Expansive soils are characterized by their ability to undergo significant volume change (shrink or swell) due to variations in moisture content. Changes in soil moisture content can result from rainfall, irrigation, pipeline leakage, surface drainage, perched groundwater, drought, or other factors. Volumetric change of expansive soil may cause excessive cracking and heaving of structures with shallow foundations, concrete slabs-on-grade, or pavements supported on these materials. Constructing Project improvements on soils known to be potentially moderately to highly expansive would have a moderate to high impact to the Project. Constructing Project improvements on soils categorized with a low expansion potential would have a low impact to Project improvements. The relative potential impact of expansive soils is low for deep foundations such as deep tower foundations, since volumetric changes of expansive soils diminish with overburden depth.

Detailed assessment of the potential for expansive soils would be evaluated during the design phase of the Project and mitigation techniques would be developed, as appropriate, to reduce the impacts related to expansive soils to low levels. Therefore, the potential residual impacts due to expansive soils are considered low with incorporation of mitigation techniques such as avoiding areas of expansive soils, overexcavation and replacement with non-expansive soil, soil treatment, moisture control, and/or specific structural design for expansive soil conditions developed during design of the Project.

7.1.11. Corrosive Soils

Based on NRCS soil data, potentially corrosive soils may be present along some segments of the proposed Project.

Corrosive soils, especially in areas of shallow groundwater that may be present in portions of the study area, can present a corrosion hazard to concrete in contact with soil, concrete and metal foundations, and other buried metal structures such as utility lines. Areas of corrosive soil could cause of premature deterioration of these underground structures or foundations. Constructing Project improvements on soils with a low corrosive potential would have a low initial impact to the improvements; constructing Project improvements on soils with a moderate corrosive potential would have a moderate initial impact to the improvements; and constructing improvements on soils known to be potentially highly corrosive would have a high initial impact to the Project. A summary of potential initial impact levels due to corrosive soils is provided below in Table 25, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

Assessment of the potential for corrosive soils would be evaluated during the design phase of the Project through soil testing procedures, and mitigation techniques would be developed, as appropriate, to reduce the impacts related to corrosive soils to low levels. Therefore, the potential residual impacts due to corrosive soils are considered low with incorporation of mitigation techniques such as avoiding areas of corrosive soils, the use of concrete resistant to sulfate exposure and selection of the appropriate type of cement and water/cement ratio, protective coatings for metallic substructures and components, and the use of alternative (corrosion resistant) materials.

TABLE 25 – SUMMARY OF POTENTIAL INITIAL IMPACTS DUE TO CORROSIVE SOILS[1]

SEGMENT	LENGTH OF Segment (Miles)	AREAS WITH AVAILABLE DATA (MILES)	LOW IMPACT CORROSIVE SOIL POTENTIAL (MILES)	MODERATE IMPACT CORROSIVE SOIL POTENTIAL (MILES)	HIGH IMPACT CORROSIVE SOIL POTENTIAL (MILES)
A	13.2	13.2	0.0	9.5	3.7
B	26.5	26.2	2.9	9.9	13.4
C	21.7	21.7	2.4	13.2	6.1
D	48.2	30.2	15.1	6.6	8.5
E	11.3	11.3	3.4	1.5	6.4
F	3.6	2.8	1.5	1.3	0.0
115th	4.8	4.7	1.8	2.8	0.0
G	21.2	6.5	2.6	3.6	0.3
2a	6.6	0.7	0.0	0.7	0.0
H	19.8	5.3	1.6	3.2	0.5
I	31.9	28.9	8.4	15.4	5.1
J	12.0	8.6	1.3	0.3	7.0
K	15.4	9.7	4.7	3.2	1.8

Notes:

[1] Data from USDA(2007b, and 2008a, b, c and d). When multiple soils occur in a single 1/10th mile, the higher potential impact corrosive value is considered.

7.1.12. Groundwater

Groundwater depths underlying the Project components are variable and are reported to range from less than 10 feet deep to more than 300 feet deep. Based on the reported depths to groundwater and anticipated depth of construction activities for new foundations for Project components, groundwater may affect portions of the proposed Project. In areas where shallow groundwater is reported to be 25 feet deep or less, groundwater is considered to have a high initial impact to the Project. Groundwater ranging from 25 to 50 feet deep is considered to have a moderate initial impact; and groundwater levels deeper than 50 feet have a low initial impact to the Project. A summary of potential initial impact levels due to groundwater is provided in Table 26, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

Subsurface construction activities for Project implementation at the site are anticipated to consist of relatively shallow excavations for roadway construction and tower pads and may involve deeper excavations for foundations and other improvements. Groundwater in excavations can cause instability of the excavations, and present a constraint to the construction of foundations. Shallow groundwater less than 50 feet deep, if encountered, can have adverse effects on the construction activities for the Project.

Due to the potentially shallow groundwater levels reported along segments of the Project, wet or saturated soil conditions may be encountered in excavations during construction. In addition, areas of shallow groundwater may be encountered where not previously reported, and areas of perched groundwater may be encountered along segments of the Project. Groundwater in excavations can cause instability of the excavations, and present a constraint to the construction of foundations. Excavations for foundations extending below the groundwater table or in areas with shallow perched groundwater may need to be cased/shored and/or dewatered to maintain stability of the excavations and provide access for construction. Saturated soils encountered in excavations below the groundwater can be difficult for the contractor to handle. Groundwater from the excavation spoils brought to the surface can contribute to soil erosion and surface water quality during construction.

Shallow groundwater can also impact ground stability, and foundation design of proposed improvements, as well as the methods and costs of construction. If not adequately monitored by the contractor, dewatering of excavations could induce consolidation of the underlying soils, which could cause differential settlement of existing structures and improvements located near the excavation. The amount of consolidation due to dewatering would depend on many factors, including the areal extent and depth of dewatering, soil type, soil density, and the methods used by the dewatering contractor. Excavations for the underground structures would need to be performed with care to reduce the potential for lateral deflection of excavation sidewalls and/or shoring, which could also cause differential movement of structures located near the excavation.

Groundwater levels may be influenced by seasonal variations, variations in ground surface topography, precipitation, irrigation practices, soil/rock types, groundwater pumping, and other factors and are subject to fluctuations. Shallow perched groundwater or groundwater seepage may be present in locations. Further study, including subsurface exploration, would be performed during the design phase to evaluate the presence of groundwater, seepage, and/or perched groundwater at the site and the potential impacts on design and construction of Project improvements. Assessment of the potential for shallow groundwater would be evaluated during the design phase of the Project and mitigation techniques would be developed, as appropriate, to reduce the impacts related to shallow groundwater to low levels. Therefore, the potential residual impacts due to shallow groundwater are considered low with incorporation of mitigation techniques such as construction dewatering.

Notes:

[1] Based on available data from CDWR (2008), and CGS Seismic Hazards Evaluation Reports.

7.1.13. Inundation from Dam Failure, Seiche or Tsunami

Based on the review of the County of Los Angeles General Plan Safety Element (1990), portions of the proposed Project segments are located in several potential dam failure inundation zones. Inundation due to dam failure could cause damage to Project improvements including erosion of earth materials which could undermine foundation support. The potential initial impacts due to inundation from dam failure are considered high. A summary of potential initial impact levels due to dam failure inundation is provided in Table 27, and is presented on a 1/10th mile basis in the Impact Assessment Table in Appendix A.

Dams and reservoirs in California are monitored by various governmental agencies (such as the State of California Division of Safety of Dams and the U.S. Army Corps of Engineers) to guard against the threat of dam failure or seiche. Current design and construction practices, and ongoing programs of review, modification, seismic retrofitting or total reconstruction of existing dams are intended to see that dams are capable of withstanding the maximum credible earthquake for the site. Due to the regulatory monitoring of dams and reservoirs, the residual impact of inundation due to dam failure is considered a low impact to the Project.

The General Plans of Los Angeles and Kern Counties did not indicate the potential for inundation due to seiche from water bodies within the Project study area. The Project site is not within an area considered to be susceptible to tsunami inundation due to the distance from the Pacific coast. Therefore, the proposed Project would not result in, or expose people to, impacts related to tsunamis.

Notes:

[1] Data from County of Los Angeles, 1990; Kern County, 2005; Kern County, 2007.

7.2 NEW 230 KV CIRCUIT

Between the proposed Haskell Canyon Switching Station and the existing Castaic Power Plant, LADWP proposes the addition of 12 miles of a new 230 kV transmission circuit onto existing Castaic – Olive 230 kV Transmission Line structures (towers 1-1 through 12-1).

The addition of a new circuit on existing towers would require many of the same activities of a new transmission line (surveying of ROW, rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, ground rod installation, and cleanup). The work would be within existing ROW, and existing access and spur roads would be utilized. The evaluation of the proposed new 230kV circuit has been incorporated into the affected environment, impact results and impact assessment sections of this preliminary evaluation as the Segment J corridor.

7.3 RECONDUCTORING

LADWP proposes the reconductoring of 76 miles of the existing BR-RIN 230 kV transmission line with larger conductors from the Barren Ridge Switching Station to Rinaldi Substation. The BR-RIN is located along Segments A, B, G, and K. From Haskell Canyon headed south to Rinaldi Substation, the BR-RIN is located on the same four-circuit structures as the Castaic-RS-J, Castaic-Sylmar, and Castaic-Olive 230 kV transmission lines.

The upgrade of the existing BR-RIN would also necessitate many of the same activities of the new transmission line (surveying of ROW, rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, ground rod installation, and cleanup). The existing line would be removed and used to pull the new conductor. Some of the towers would need to be modified or replaced, and/or foundations reinforced, to carry the additional weight of the new heavier conductor. The work would remain within the existing ROW.

Since the reconductoring of the BR-RIN 230 kV transmission line may involve activities similar to construction of the proposed new transmission line, the evaluation of the reconductoring of the existing transmission line is presented in the affected environment, impact results and impact assessment sections of this preliminary evaluation as Segments A, B, G and K.

7.4 NEW HASKELL CANYON SWITCHING STATION

As a component of the BRRTP, LADWP proposes the construction of the new Haskell Canyon Switching Station in Haskell Canyon, south of the ANF at the convergence of several existing and proposed 230 kV transmission lines (the existing BR-RIN, the proposed double-circuit Barren Ridge-Haskell Canyon, existing Castaic-Northridge, Castaic-Sylmar, Castaic-Olive, and the proposed Castaic to Haskell Canyon). The station would be 500 feet by 600 feet to accommodate the necessary electrical equipment. Construction of the new Haskell Canyon Switching Station would consist of clearing of access roads, site grading and development, installation of electrical conduits for equipment power and control, and installation of structures and equipment. Equipment needed for station construction would include backhoes, drill rigs, concrete trucks, flatbeds and trucks. Cranes, man-lifts, portable welding units, line trucks and mechanic trucks would also be utilized.

Evaluation of the affected environment for the proposed new Haskell Canyon Switching Station is presented in the Affected Environment section of this preliminary evaluation. In summary, review of referenced soil, geologic, and seismic background data indicates that the Haskell Canyon site is underlain by Tertiary marine and non-marine sedimentary formations. The USDA soil type underlying the site is mapped as the Calciserollic Xerochrepts-Calleguas family-Modesto family, which has a high sensitivity rating based on the severe erosion potential. Distinctive geologic features were not observed at the Haskell Canyon site. The site is not crossed by a known active fault, and the potential for surface rupture is considered low. Potential seismic ground shaking at the site is on the order of 0.40g. The site is not located in a liquefaction hazard zone or earthquake-induced landslide hazard zone based on the State of California Seismic Hazards Zones map. Landslides are mapped and were observed in the vicinity of the Haskell Canyon site. There are no USDA data available regarding the potential for expansive soils or corrosive soils at the site. There are no data available regarding groundwater levels at the Haskell Canyon site. The Haskell Canyon site is not located in a dam failure inundation zone.

Assessment of the potential initial impacts for construction of the new Haskell Canyon Switching Station includes the following impact results:

- The soil sensitivity rating at Haskell Canyon has been categorized as high, and the initial impact of erosion of soils at this site is considered high.
- Highly sensitive distinctive geologic features were not observed at the Haskell Canyon site. Based on the sedimentary rock formations present at the Haskell Canyon site, the initial impact to distinctive geologic features is considered moderate.
- The Haskell Canyon site is not located in an Earthquake Fault Zone and the initial impacts related to surface fault rupture are considered low.
- The design PGA for the proposed Haskell Canyon station is 0.40g. The ground shaking potential at the station site is considered to have a moderate initial impact.
- The Haskell Canyon site is not located in a potential liquefaction zone based on the State of California Seismic Hazards Zones map, and the initial impacts related to liquefaction are considered low.
- The Haskell Canyon site is not located in a potential earthquake-induced landslide zone based on the State of California Seismic Hazards Zones map, and the initial impacts related to earthquake-induced landslides are considered low.
- Landslides are shown on geologic maps and landslides were observed during geologic field reconnaissance in the vicinity of the Haskell Canyon Switching Station site. Constructing the switching station on a landslide would have a high initial impact on the Project.

- There is a potential for compressible soils to be present at the Haskell Canyon site. Constructing the switching station on soils known to have a potential for settlement would have a high initial impact to the Project
- NRCS data regarding the expansive potential of surface soils at the Haskell Canyon site have not been reported. However, based on the potential presence of clay shale units at this site, moderately to highly expansive soils may be present. Constructing the switching station on known expansive soils would have a high initial impact on the Project.
- NRCS data regarding the corrosive potential of surface soils at the Haskell Canyon site have not been reported. However, corrosive soils may be present at the site, and could have a high initial impact on the Project.
- There are no data readily available regarding groundwater levels at the Haskell Canyon site. However, shallow groundwater or perched groundwater may be present at the site, and could have a high initial impact to the Project if encountered during construction.
- The Haskell Canyon site is not located in a dam failure inundation zone, and the initial impacts related to dam failure inundation are considered low.

During the design phase for the switching station site, the potential Project impacts would be evaluated through data review, geologic reconnaissance and subsurface exploration, as appropriate. The results of the site-specific evaluation would be incorporated into the design of the switching station. Through this process, the highly sensitive geologic resources that could be affected would be located and mitigation would be implemented to reduce the impacts to low levels; and the potential geologic and seismic hazards would be considered relative to the construction of the switching station, and mitigation techniques would be developed to reduce the impacts to low levels that would be appropriate for design. With the implementation of the appropriate mitigations, the initial impacts to geologic resources and impacts related to potential seismic and geologic hazards at the switching station site can be reduced to low residual levels.

7.5 EXPANSION OF BARREN RIDGE SWITCHING STATION

LADWP proposes expansion of the existing Barren Ridge Switching Station to the east side by 235 feet by 500 feet, for a total station size of 485 feet by 500 feet (5.6 acres). The expansion area of the station would include additional electrical structures for additional lines, a material staging area, a roadway within the station, and a drainage area. Expansion of the existing switching station would be similar to the construction of the Haskell Canyon Switching Station. Site construction activities would consist of installation of reinforced concrete foundations, installation of electrical conduits for equipment power and control, and installation of structures and equipment. Equipment needed for station construction would include backhoes, drill rigs, concrete trucks, flatbeds and trucks. Cranes, man-lifts, portable welding units, line trucks and mechanic trucks would also be utilized.

Evaluation of the affected environment for expansion of the Barren Ridge Switching Station (Barren Ridge) is presented in the Affected Environment section of this preliminary evaluation. In summary, review of referenced soil, geologic, and seismic background data indicates that the Barren Ridge site is underlain by Quaternary alluvial sediments. The USDA soil type underlying the site is mapped as the Arizo gravelly loamy sand, which has a low sensitivity rating based on the slight erosion potential. Distinctive geologic features were not observed at the Barren Ridge site. The site is not crossed by a known active fault, and the potential for surface rupture is considered low. Potential seismic ground shaking at the site is on the order of 0.52g. The site is not located in a liquefaction hazard zone or earthquake-induced landslide hazard zone based on the State of California Seismic Hazards Zones map. There are no landslides at the Barren Ridge site. There are no USDA data available regarding the potential for expansive soils at the site. USDA data indicate a low to moderate corrosive soil potential at the Barren Ridge site. There are no data available regarding groundwater levels at the Barren Ridge site. The Barren Ridge site is not located in a dam failure inundation zone.

Assessment of the potential initial impacts for expansion of the Barren Ridge Switching Station includes the following impact results:

- The soil sensitivity rating at Barren Ridge has been categorized as low, and the impact of erosion of soils at this site is considered low.
- Distinctive geologic features were not observed at Barren Ridge, and the initial impact to distinctive geologic features is considered low.
- The Barren Ridge site is not located in an Earthquake Fault Zone and the initial impacts related to surface fault rupture are considered low.
- The design PGA for the proposed Barren Ridge station is 0.52g. The ground shaking potential at the station site is considered to have a high initial impact.
- The Barren Ridge site is not located in a potential liquefaction zone based on the State of California Seismic Hazards Zones map, and the initial impacts related to liquefaction are considered low.
- The Barren Ridge site is not located in a potential earthquake-induced landslide zone based on the State of California Seismic Hazards Zones map, and the initial impacts related to earthquake-induced landslides are considered low.
- There are no landslides at the Barren Ridge site.
- There is a potential for compressible soils to be present at the Barren Ridge site. Constructing the expanded switching station on soils known to have a potential for settlement would have a high initial impact to the Project
- NRCS data regarding the expansive potential of surface soils at the Barren Ridge site have not been reported. However, based on the sandy nature of the surface soils mapped at the site and observed during field reconnaissance, the expansive potential of the soils at this site is considered low, and is considered to have a low initial impact to the Project.
- The corrosive soil potential at the Barren Ridge site has been categorized as low for concrete and moderate for steel according to NRCS data. Therefore, corrosive soils may be present at the site, and could have a moderate initial impact on the Project.
- There are no data available regarding groundwater levels at the Barren Ridge site. However, shallow groundwater or perched groundwater may be present at the site, and could have a high initial impact to the Project if encountered during construction.
- The Barren Ridge site is not located in a dam failure inundation zone, and the initial impacts related to dam failure inundation are considered low.

During the design phase for the expanded switching station site, the potential Project impacts would be evaluated through data review, geologic reconnaissance and subsurface exploration, as appropriate. The results of the site specific evaluation would be incorporated into the design of the expanded switching station. Through this process, the highly sensitive geologic resources that could be affected would be located and mitigation would be implemented to reduce the impacts to low levels; and the potential geologic and seismic hazards would be considered relative to the construction of the expanded switching station, and mitigation techniques would be developed to reduce the impacts to low levels that would be appropriate for design. With the implementation of the appropriate mitigations, the initial impacts to geologic resources and impacts related to potential seismic and geologic hazards at the expanded switching station site can be reduced to low residual levels.

8.0 ALTERNATIVES

NEPA and CEQA both require consideration of a reasonable range of alternatives to the Proposed Action that would feasibly attain most of the basic objectives of the Project, but avoid or substantially lessen any of the significant or adverse effects of the Project.

8.1 DEVELOPMENT OF ALTERNATIVES

A range of alternatives were identified through a siting analysis, the scoping process, and supplemental studies and consultations. A full discussion of alternatives development can be found in the Alternatives Development Report (POWER 2010).

The regional siting analysis identified nine routing opportunities (Segments A through I) for the new 230 kV transmission line between Barren Ridge Switching Station and the proposed Haskell Canyon Switching Station. Some of the routing opportunities or segments were adjusted or modified based on public input and preliminary environmental review, and preliminary electrical system studies. Each of the nine segments are discussed in detail, including impact analysis, in Section 7.0 of this report. Several of these segments were not used in the formation of alternatives as discussed below.

Segment E was recommended for elimination from analysis in the EIS/EIR. The Segment would require an additional 6.5 miles of transmission line in comparison to the Proposed Action and would not significantly reduce or avoid impacts to air quality, biological, cultural, visual, and water resources. Segment H was also recommended for elimination, due to increased impacts to air quality and noise, along with safety concerns, related to helicopter construction. Cumulative effects for the Project would also increase because of the further disturbance of revegetated and rehabilitated areas and potential for impacts from three transmission line projects in the same vicinity.

Eight routing opportunities (Segments A, B, C, D, F, G, 2a, and I) were combined to create end-to-end routing alternatives for the proposed double-circuit 230 kV transmission line between Barren Ridge Switching Station and the proposed Haskell Canyon Switching Station. In addition to routing segments, each Alternative discussed within this section would include other Project components as discussed earlier within this report. These include the addition of a new circuit on existing towers between Castaic Power Plant and Haskell Canyon, reconductoring of the existing BR-RIN transmission line, construction of a new Haskell Canyon Switching Station, and expansion of the existing Barren Ridge Switching Station. Impact assessment and impact results for each of the other Project components listed above, and which are common to each of the Alternatives, are described in Section 7.0. Descriptions and impact assessment of the routing alternatives follow in the sections below.

8.2 ALTERNATIVES DESCRIPTION

The following alternatives were identified as a reasonable range of alternatives to the Project that would feasibly attain most of the basic objectives of the Project, but avoid or substantially lessen any of the significant or adverse effects of the Project.

8.2.1. Action Alternatives

In addition to a new double-circuit 230 kV transmission line between the Barren Ridge and Haskell Canyon switching stations, whose route would vary among the action Alternatives, the four action Alternatives would include the following common components: the expansion of the existing Barren Ridge Switching Station, construction of a new Haskell Canyon Switching Station, reconductoring of the existing 230 kV transmission line from the Barren Ridge Switching Station to Rinaldi Substation, and the addition of a new 230 kV circuit on existing towers between the Castaic Power Plant and Haskell Canyon Switching Station. Refer to Figure 8-1.

Alternative 1 (Segments A, C, and D)

The Alternative 1 230 kV double-circuit transmission line comprises the preliminary routing Segments A, C, and D, and is the longest Alternative, at 83 miles long. It would run from the Barren Ridge Switching Station to the unincorporated community of Mojave, while paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines. It would continue south-southwest to parallel the Los Angeles Aqueduct to Lancaster Road, where it would travel west to the I-5 utility corridor. It would then run southeast along LADWP's existing Castaic – Rinaldi corridor to the proposed Haskell Canyon Switching Station.

Helicopter Mitigation

Within the ANF where the terrain is steep and access is limited, the USFS would require that the new double-circuit 230 kV structures be constructed with the use of helicopters (such as the Hughes 500 or Bell 212, or Sikorsky Skycrane). Refer to Figure 8-2, the Identified Helicopter Mitigation Locations Map, which illustrates the identified locations for this mitigation. The use of helicopters for the construction of transmission tower structures would eliminate the need for new access roads to structure locations, and would therefore minimize land disturbance associated with crane pads, structure laydown areas, and the trucks and tractors used for delivery of structures to sites. However, the following site and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas, tower structure vegetation clearing, guard structures at major crossings, wire stringing sites, pullouts, and temporary access roads.

Geological Considerations

The proposed Alternative 1 route begins at the Barren Ridge Switching Station in the Mojave Desert and travels southwest along the northwestern edge of the Mojave Desert and Antelope Valley crossing areas underlain by Quaternary alluvial deposits. It crosses the San Andreas Fault Rift Zone near the western boundary of the Project study area and then runs southeast over steep mountainous areas in the ANF underlain by areas of Mesozoic granitic rock, and by Plio-Pleistocene non-marine and Tertiary marine sedimentary formations. Quaternary alluvial deposits are present in canyons and drainage areas along Alternative 1. The alternative crosses San Francisquito Canyon near the southern end of Alternative 1 and ends at the proposed Haskell Canyon Switching Station underlain by Tertiary sedimentary formations.

Alternative 1 would cross two active faults with the potential for surface rupture, including the active Garlock fault zone at the beginning of the route near the Barren Ridge Switching Station, and the active San Andreas fault zone. Potential ground shaking along Alternative 1 due to seismic activity would range from 0.30g to 0.60g. Liquefaction hazard zones are located near the southern end of the proposed alternative near the proposed Haskell Canyon Switching Station. Mapped landslides and Earthquake-Induced Landslide Hazard Zones are located in the steep ANF in the southern portion of the alternative. Variable areas of slight to very severe erosion potential exist along the proposed alternative. An area of high expansion potential is located along the existing Castaic – Rinaldi corridor. Areas of low to high corrosive soil potential exist along the proposed alternative. Reported groundwater depths along this proposed alternative are on the order of 138 to 336 feet deep in the Antelope Valley area; a 0.2 mile portion of Alternative 1 has an area of reported shallow groundwater 10 feet deep along the existing Castaic – Rinaldi corridor. 1.5 miles of Alternative 1 are located within a potential dam failure inundation zone due to the proximity to Castaic Lake and Bouquet Reservoir.

A summary of the affected environment for Alternative 1 is presented below in Table 28. In general, Alternative 1 would have lower levels of potential ground shaking than Alternatives 2, 2a and 3; would cross fewer liquefaction zones than proposed Alternatives 2, 2a and 3; would cross fewer potential landslide areas than Alternative 3 and more potential landslide areas than Alternative 2 and 2a; and would cross more areas of severe to very severe erosion potential than Alternatives 2, 2a and 3.

Alternative 2 (Segments A, B, and G) –LADWP's Proposed Action

Alternative 2, LADWP's Proposed Action, comprises Segments A, B, and G and is 61 miles long. It begins at the Barren Ridge Switching Station and runs south, paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines. It travels south from the unincorporated community of Mojave, California through the Antelope Valley and approximately one mile east of the Antelope Valley California Poppy Reserve before continuing onto National Forest System lands and ending at the proposed Haskell Canyon Switching Station. The entire route would remain within designated utility corridors and would parallel existing transmission lines. Refer to Section 1.2, Project Description, for a full description of this Alternative.

Geological Considerations

The proposed Alternative 2 route begins at the Barren Ridge Switching Station in the Mojave Desert and travels southwest along the northwestern edge of the Mojave Desert and then runs south across the Antelope Valley traversing areas underlain by Quaternary alluvial deposits. Alternative 2 crosses the steep Ritter Ridge/Portal Ridge area and San Andreas Fault Rift Zone in the Leona Valley where Mesozoic granitic rocks, Pelona Schist and Pliocene sedimentary formations underlie the proposed route. It runs south/southeast over the steep, mountainous ANF and through San Francisquito Canyon, Dry Canyon and Haskell Canyon. The ANF portion of Alternative 2 south of the San Andreas Fault Rift Zone is underlain by areas of Mesozoic granitic rock, Precambrian metamorphic rock, Pelona Schist, Tertiary marine and non-marine sedimentary formations, and Quaternary alluvium.

Alternative 2 would cross two active faults with the potential for surface rupture, including the active Garlock fault zone at the beginning of the route near the Barren Ridge Switching Station, and the active San Andreas fault zone. Potential ground shaking along this alternative due to seismic activity would range from 0.25g to 0.80g. Liquefaction hazard zones are located in the southern Antelope Valley and San Andreas Rift Zone areas. Mapped landslides and Earthquake-Induced Landslide Hazard Zones are located in the steep ANF in the southern portion of the alternative. Variable areas of slight to very severe erosion potential exist along the proposed alternative. Areas of low to high corrosive soil potential exist along the proposed alternative. Reported groundwater depths along this proposed alternative are on the order of 172 to 295 feet deep in the Antelope Valley area, and 10 to 184 feet deep in the ANF. 1.4 miles of Alternative 2 are located within a potential dam failure inundation zone due to the proximity to Fairmont Reservoir and Bouquet Reservoir.

A summary of the affected environment for Alternative 2 is presented below in Table 28. In general, Alternative 2 would have a shorter crossing of the San Andreas fault zone (and therefore would cross fewer miles of Earthquake Fault Zones) than Alternatives 1 and 3; would cross fewer liquefaction zones than Alternative 3 and cross more liquefaction zones than Alternative 1; would cross fewer potential landslide areas than Alternatives 1 and 3 and cross slightly more potential landslide areas that Alternative 2a; and would have fewer areas of severe to very severe erosion potential than Alternatives 1, 2a and 3.

Alternative 2a (Segments A, B, G and 2a)

The 230 kV double-circuit transmission line in Alternative 2a comprises the preliminary routing Segments A, B, and G, but includes a re-route (Segment 2a) avoiding the unincorporated community of Green Valley. It is 63 miles long and would be very similar to the Proposed Action (Alternative 2), with 56 miles of the same alignment. Alternative 2a would begin at the Barren Ridge Switching Station and run south, paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines. It would travel south from the unincorporated community of Mojave through the Antelope Valley and approximately one mile east of the Antelope Valley California Poppy Reserve before continuing onto NFS lands and ending at the proposed Haskell Canyon Switching Station. The route would remain within designated utility corridors and would parallel existing transmission lines, with the exception of the nearly seven miles that would be routed around the unincorporated community of Green Valley. Segment 2a would create a new utility corridor through the ANF. The re-route would rejoin Segment G south of the unincorporated community of Green Valley before continuing south and ending at the proposed Haskell Canyon Switching Station.

Three-Circuit Tower Mitigation

In areas where there are ROW expansion constraints and where LADWP has existing 230 kV transmission lines, LADWP is proposing to construct three-circuit towers to carry the existing BR-RIN circuit and two new BR-HC circuits. This would avoid various impacts including the acquisition of residential property in the unincorporated communities of Willow Springs (milepost 27.1 to 27.6) and Elizabeth Lake and Green Valley (milepost 44.6 to 46 and milepost 50.8 to 51.7). This mitigation would be utilized in the same areas that were identified for Three-Circuit Tower Mitigation for the Proposed Project, with the exception of approximately five miles through the unincorporated community of Green Valley, which would not utilize this mitigation. These areas are illustrated in 1-7, the Three-Circuit Tower Mitigation Map.

Helicopter Mitigation

Within the ANF where the terrain is steep and access is limited, the USFS would require that the new double-circuit 230 kV structures be constructed by the use of helicopter. Refer to Figure 8-2, Identified Helicopter Mitigation Locations, which illustrates the identified locations for this mitigation. The use of helicopters for the construction of transmission tower structures would eliminate the need for new access roads to structure locations, and would therefore minimize land disturbance associated with crane pads, structure laydown areas, and the trucks and tractors used for delivery of structures to sites. However, the following site and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas, tower structure vegetation clearing, guard structures at major crossings, wire stringing sites, pullouts, and temporary access roads. The estimated sizes of these auxiliary sites (temporary and permanent) and additional construction information is detailed above in the description of the Proposed Action (Alternative 2) and in Appendix C.

Geological Considerations

The Segment 2a portion of Alternative 2a would cross areas of steep terrain along Leona Divide, Grass Mountain and a ridge area north of Portal Canyon where it is predominantly underlain by Mesozoic granitic rock and Precambrian metamorphic rock. Segment 2a would not cross a known active fault. Potential ground shaking along this alternative due to seismic activity would range from 0.60g to 0.80g. No liquefaction hazard zones are mapped along Segment 2a. No landslides are shown on geologic maps reviewed for this evaluation. Earthquake-Induced Landslide Hazard Zones are located on the steep terrain along this alternative. Segment 2a is underlain by areas of severe to very severe erosion potential. Areas of moderate corrosive soil potential exist along the proposed alternative. Groundwater data was not readily available for this alternative in the ANF. No potential dam failure inundation zones are mapped along Segment 2a.

A summary of the affected environment for Alternative 2a is presented below in Table 28. In general, Alternative 2a would have a shorter crossing of the San Andreas fault zone (and therefore would cross fewer miles of Earthquake Fault Zones) than Alternatives 1 and 3; would cross fewer liquefaction zones than Alternative 3 and cross more liquefaction zones than Alternative 1; would cross fewer potential landslide areas than Alternatives 1, 2 and 3; and would cross fewer areas of severe to very severe erosion potential than Alternatives 1 and 3 and cross more potential areas of severe to very severe erosion potential than Alternative 2. In comparing Alternative 2 and 2a, Alternative 2a would cross 0.3 fewer miles of earthquake-induced landslide hazard zones, and would cross 1.9 more miles of severe to very severe erosion potential.

Alternative 3 (Segments A, B, F, and I)

The proposed 230 kV double-circuit transmission line in Alternative 3 comprises preliminary routing Segments A, B, F, and I. It is 76 miles long and would begin at the Barren Ridge Switching Station and run south, paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI lines. It would travel south from the unincorporated community of Mojave through the Antelope Valley and approximately one mile east of the Antelope Valley California Poppy Reserve before continuing southeast past SCE's Antelope Substation. The route would then travel toward the city of Palmdale, parallel to SCE's existing high-voltage transmission lines. It would make a sharp turn to the south to parallel LADWP's existing Victorville – Rinaldi 500 kV and Adelanto – Rinaldi 230 kV transmission lines. This Alternative would then parallel these transmission lines west, crossing two miles of the ANF. The Alternative would then parallel LADWP's 500 kV PDCI line north to the proposed Haskell Canyon Switching Station.

Three-Circuit Tower Mitigation

In areas where there are ROW expansion constraints and where LADWP has existing 230 kV transmission lines, LADWP is proposing to construct three-circuit towers to carry the existing BR-RIN circuit and two new BR-HC circuits. This would avoid various impacts including the acquisition of residential property in the unincorporated communities of Willow Springs (milepost 27.1 to 27.6). Please refer to the small inset map on Figure 1-7.

Avenue L Re-route

To avoid acquisition of private property, a portion of Alternative 3 from mile marker 45.2 to 46.7 was moved to parallel a smaller distribution line south along 90th Street West and then east along West Avenue "L." Refer to Figure 8-3, Avenue L Re-route on Alternative 3.

Geological Considerations

The proposed Alternative 3 route begins at the Barren Ridge Switching Station in the Mojave Desert and travels southwest along the northwestern edge of the Mojave Desert and then runs south across the Antelope Valley traversing areas underlain by Quaternary alluvial deposits. Alternative 3 crosses the steep Portal Ridge area and San Andreas Fault Rift Zone in the Leona Valley where Pelona Schist predominantly underlies the route. It runs west/southwest over the steep, mountainous Sierra Pelona and through Mint Canyon, Bouquet Canyon and Haskell Canyon. The Sierra Pelona portion of Alternative 3 south of the Antelope Valley is underlain by areas of Pelona Schist, granitic rock, and Tertiary marine and non-marine sedimentary formations. Quaternary alluvial deposits are present in canyons and drainage areas along Alternative 3.

Alternative 3 would cross two active faults with the potential for surface rupture including the active Garlock fault zone at the beginning of the route near the Barren Ridge Switching Station, and the active San Andreas fault zone. Potential ground shaking along this alternative due to seismic activity would range from 0.25g to 0.80g. Liquefaction hazard zones are located in the San Andreas Rift Zone and in low-lying canyon areas in the southern part of the alternative. Mapped landslides and Earthquake-Induced Landslide Hazard Zones are located in the steep Sierra Pelona in the southern portion of the alternative. Variable areas of slight to very severe erosion potential exist along the proposed alternative. Areas of low to high corrosive soil potential exist along the proposed alternative. Reported groundwater depths along this proposed alternative are on the order of 10 to 295 feet deep in the Antelope Valley area, and 10 to 326 feet deep in the portions of the Sierra Pelona and canyon areas in the southern portion of the alternative. 1.7 miles of Alternative 3 are located within a potential dam failure inundation zone due to the proximity to Fairmont Reservoir.

A summary of the affected environment for Alternative 3 is presented below in Table 28. In general, Alternative 3 would cross more liquefaction zones than proposed Alternatives 1 2 and 2a; would cross more potential landslide areas than Alternatives 1, 2 and 2a; and would cross fewer areas of severe to very severe erosion potential than Alternative 1 and cross more areas of severe to very severe erosion potential than Alternatives 2 and 2a.

8.2.2. Summary Description of Action Alternatives

A summary of the affected environment for the proposed action alternatives is shown below in Table 28. Table 28 is presented for comparison of the proposed action alternatives and was created by summarizing the potential geologic and seismic hazards and geologic resources in the affected environment presented in Section 5.0 of this report and in Tables 1 through 13.

TABLE 28 – SUMMARY OF AFFECTED ENVIRONMENT FOR PROPOSED ALTERNATIVES

8.2.3. No Action Alternative

Under the No Action Alternative, the construction of a new 230 kV transmission line, the addition of a new circuit on existing structures from Haskell Canyon to the Castaic Power Plant, the reconductoring of the existing BR-RIN transmission line, the construction of a new Haskell Canyon Switching Station, and the expansion of the existing Barren Ridge Switching Station would not occur. LADWP currently maintains an estimated 147 miles of existing access roads in the Project area, 97 of which are located within the ANF. Current, on-going operation and maintenance activates for existing facilities in the Project area would continue. The EIS/EIR must address the resulting environmental effects from taking no action and compare them to the effects of permitting the Proposed Action or an Alternative to the Proposed Action.

8.3 IMPACT ASSESSMENT—ROUTING ALTERNATIVES

A comparison summary of the initial impacts affecting the proposed alternatives is presented in the following section. The proposed routing alternatives were evaluated by adding the miles of impacts in the various geologic resource and potential geologic/seismic hazard categories for the Project segments that comprise the alternatives. Alternative 1 was evaluated by adding the impacts for Segments A, C and D; Alternative 2a was evaluated by adding the impacts for Segments A, B, G, and 2a; and Alternative 3 was evaluated by adding the impacts for Segments A, B, F and I.

8.4 IMPACT RESULTS—ROUTING ALTERNATIVES

A comparison summary of the initial impacts affecting the proposed routing Alternatives 1, 2, 2a and 3 is presented in Tables 29 through 39. The impact of the No Action alternative is also presented in the following tables. A discussion of the results of the impact assessment for the proposed routing alternatives follows each table.

TABLE 29 – SUMMARY OF THE PROPOSED ALTERNATIVE POTENTIAL INITIAL IMPACTS TO SOILS[1]

PROPOSED ALTERNATIVE	TOTAL LENGTH OF ALTERNATIVE (MILES)	MILES OF LOW SENSITIVITY/LOW IMPACT LEVEL AREAS TRAVERSED (PERCENT OF TOTAL LENGTH)	MILES OF MODERATE SENSITIVITY/ MODERATE IMPACT LEVEL AREAS TRAVERSED (PERCENT OF TOTAL LENGTH)	MILES OF HIGH SENSITIVITY/HIGH IMPACT LEVEL AREAS TRAVERSED (PERCENT OF TOTAL LENGTH)
Alternative 1	83.1	52.2 (62.8%)	4.9 (5.9%)	26.0 (31.3%)
Alternative 2	60.7	43.7 (71.8%)	1.9 (3.1%)	15.3 (25.1%)
Alternative 2a	62.5	42.7 (68.4%)	2.5 (4.0%)	17.2 (27.6%)
Alternative 3	75.5	48.0 (63.8%)	7.0 (9.3%)	20.2 (26.9%)
No Action	0.0	0.0	0.0	0.0

Notes:

[1] Data from USDA 2008d.

Table 29 shows that Alternative 2 would have fewer miles (and lower percent of total length) of high impact to highly sensitive soils than Alternatives 1, 2a and 3. Alternative 1 would have more miles of high impact (and higher percent of total length) than the other proposed alternatives.

TABLE 30 – SUMMARY OF THE PROPOSED ALTERNATIVE POTENTIAL INITIAL IMPACTS TO DISTINCTIVE GEOLOGIC FEATURES[1]

PROPOSED ALTERNATIVE	TOTAL LENGTH OF ALTERNATIVE (MILES)	LOW IMPACT LEVEL AREAS TRAVERSED (MILES)	MODERATE IMPACT LEVEL AREAS TRAVERSED (MILES)	HIGH IMPACT LEVEL AREAS TRAVERSED (MILES)
Alternative 1	83.1	51.9	31.2	0.0
Alternative 2	60.7	44.2	16.7	0.0
Alternative 2a	62.5	44.2	18.2	0.0
Alternative 3	75.5	49.6	23.7	0.4
No Action	0.0	0.0	0.0	0.0

Notes:

[1] Dibblee, 1997c, 1997f, 2002b. field observations.

Table 30 shows that Alternative 3 would have 0.4 mile of high impact to distinctive geologic features, while Alternatives 1, 2 and 2a would not traverse areas of high impact to distinctive geologic features. Due to its shorter total length, Alternative 2 would have fewer miles of moderate level impact to distinctive geologic features than Alternatives 1, 2a and 3.

TABLE 31 – SUMMARY OF THE PROPOSED ALTERNATIVE POTENTIAL INITIAL IMPACTS DUE TO EARTHQUAKE FAULT ZONES

PROPOSED ALTERNATIVE	TOTAL LENGTH OF ALTERNATIVE (MILES)	HIGH IMPACT LEVEL EARTHQUAKE FAULT ZONES TRAVERSED (MILES)[1]
Alternative 1	83.1	2.9
Alternative 2	60.7	2.3
Alternative 2a	62.5	2.3
Alternative 3	75.5	2.9
No Action	0.0	None

Notes:

[1] Hart and Bryant, 1997. (formerly Alquist-Priolo Special Studies Zones)

Table 31 shows that Alternatives 2 and 2a would traverse fewer miles of high impact earthquake fault zones than both Alternatives 1 and 3. This is due in part to the manner in which the proposed alternatives traverse the San Andreas fault zone, wherein Alternatives 2 and 2a cross perpendicular to the fault zone and Alternatives 1 and 3 traverse diagonally.

TABLE 32 – SUMMARY OF THE PROPOSED ALTERNATIVE POTENTIAL INITIAL IMPACTS DUE TO GROUND SHAKING

PROPOSED ALTERNATIVE	APPROXIMATE GROUND SHAKING POTENTIAL[1] (% OF THE ACCELERATION DUE TO GRAVITY, g)	TOTAL LENGTH OF ALTERNATIVE (MILES)	LOW IMPACT LEVEL AREAS TRAVERSED (MILES)	MODERATE IMPACT LEVEL AREAS TRAVERSED (MILES)	HIGH IMPACT LEVEL AREAS TRAVERSED (MILES)
Alternative 1	0.30 – 0.60	83.1	0.0	69.7	13.4
Alternative 2	0.25 – 0.80	60.7	2.7	48.2	10.0
Alternative 2a	0.25 – 0.80	62.5	2.7	43.4	16.3
Alternative 3	0.25 – 0.80	75.5	2.7	55.9	16.6
No Action	N/A	0.0	0.0	0.0	0.0

Notes:

[1] USGS (2002rev) data; and USGS (2008) Ground Motion Calculator (for Switching Stations).

Table 32 shows that Alternative 2 would traverse fewer miles of high impact ground shaking areas than Alternatives 1, 2a and 3. This is due in part to the manner in which the proposed alternatives traverse the ground shaking level contours in the southern part of the Project study area shown on Figure 6. The ground shaking level contours shown on Figure 6 are roughly parallel to the alignment of the San Andreas fault zone, and higher levels of ground shaking occur closer to the fault zone. Since Alternatives 2 and 2a cross roughly perpendicular to the San Andreas fault zone, they depart from the high ground shaking areas in a shorter distance and have fewer miles of high impact areas. Conversely, Alternatives 1 and 3 traverse diagonally to the San Andreas fault zone, and have a longer distance of departure from the high impact areas. Alternative 2a has more miles of high impact areas traversed than Alternative 2 due to the alignment of Segment 2a, which also has a roughly diagonal orientation to the San Andreas fault zone.

TABLE 33 – SUMMARY OF THE PROPOSED ALTERNATIVE POTENTIAL INITIAL IMPACTS DUE TO LIQUEFACTION HAZARD ZONES

PROPOSED ALTERNATIVE	TOTAL LENGTH OF ALTERNATIVE (MILES)	AVAILABLE DATA (MILES)[1]	HIGH IMPACT LEVEL LIQUEFACTION HAZARD ZONES TRAVERSED (MILES)[1]	RATIO OF LIQUEFACTION ZONES TO AVAILABLE DATA
Alternative 1	83.1	8.8	1.2	13.6%
Alternative 2	60.7	16.2	1.9	11.7%
Alternative 2a	62.5	18.6	1.9	10.2%
Alternative 3	75.5	41.7	10.4	24.9%
No Action	0.0	0.0	None	0.0%

Notes:

[1] Data from CGS Seismic Hazards Mapping Program for available quadrangles in the study area (some quadrangles and data not available

Table 33 shows that Alternative 1 would traverse fewer miles of high impact liquefaction hazard zones than Alternatives 2, 2a and 3. However, Alternative 1 also has fewer miles of available liquefaction zone data than the other alternatives, and when comparing the ratio of miles of liquefaction zones to the miles of available data along the proposed alternatives, the data show that Alternative 2a would have a lower ratio percentage of liquefaction zones than the other proposed alternatives. The data show that Alternative 2 would have a lower ratio percentage than Alternatives 1 and 3. Alternative 3 would traverse more miles and has a higher ratio percentage of liquefaction zones than the other proposed alternatives.

TABLE 34 – SUMMARY OF THE PROPOSED ALTERNATIVE POTENTIAL INITIAL IMPACTS DUE TO MAPPED LANDSLIDES

PROPOSED ALTERNATIVE	TOTAL LENGTH OF ALTERNATIVE (MILES)	AVAILABLE DATA (MILES)[1]	HIGH IMPACT LEVEL LANDSLIDE AREAS TRAVERSED (MILES)[1]	RATIO OF MAPPED LANDSLIDES TO AVAILABLE DATA
Alternative 1	83.1	26.0	6.6	25.4%
Alternative 2	60.7	27.4	0.2	0.7%
Alternative 2a	62.5	28.9	0.2	0.7%
Alternative 3	75.5	35.5	4.1	11.5%
No Action	0.0	0.0	None	0.0%

Notes:

[1] Data from available geologic maps by Dibblee; and from CGS Seismic Hazards Zones Reports for available quadrangles in the study area (some quadrangles and data not available).

Table 34 shows that Alternatives 2 and 2a would traverse fewer miles of high impact mapped landslide areas than Alternatives 1 and 3. In addition, when comparing the ratio of miles of mapped landslide areas to the miles of available data along the proposed alternatives, the data show that Alternatives 2 and 2a would have a lower ratio percentage of mapped landslide areas than the other proposed alternatives. The data show that Alternative 1 would traverse more miles and has a higher ratio percentage of mapped landslide areas than the other proposed alternatives.

TABLE 35 – SUMMARY OF THE PROPOSED ALTERNATIVE POTENTIAL INITIAL IMPACTS DUE TO EARTHQUAKE-INDUCED LANDSLIDE HAZARD ZONES

PROPOSED ALTERNATIVE	TOTAL LENGTH OF ALTERNATIVE (MILES)	AVAILABLE DATA (MILES)1	HIGH IMPACT LEVEL EARTHQUAKE-INDUCED LANDSLIDE AREAS TRAVERSED (MILES)[1]	RATIO OF EARTHQUAKE-INDUCED LANDSLIDE AREAS TO AVAILABLE DATA
Alternative 1	83.1	8.8	5.6	63.6%
Alternative 2	60.7	16.2	2.6	16.0%
Alternative 2a	62.5	18.6	2.3	12.4%
Alternative 3	75.5	41.7	18.8	45.1%
No Action	0.0	0.0	None	0.0%

Notes:

[1] Data from CGS Seismic Hazards Zones Reports for available quadrangles in the study area (some quadrangles and data not available).

Table 35 shows that Alternative 2a would traverse fewer miles of high impact earthquake-induced landslide hazard zones than Alternatives 1, 2 and 3. In addition, when comparing the ratio of miles of earthquake-induced landslide hazard zones to the miles of available data along the proposed alternatives, the data show that Alternative 2a would have a lower ratio percentage of earthquake-induced landslide hazard zones than the other proposed alternatives. The data show that Alternative 3 would traverse more miles of earthquake-induced landslide hazard zones than the other proposed alternatives. When comparing the ratio of miles of earthquake-induced landslide hazard zones to the miles of available data, the data show that Alternative 1 has a higher ratio percentage of earthquake-induced landslide hazard zones than the other proposed alternatives.

TABLE 36 – SUMMARY OF THE PROPOSED ALTERNATIVE POTENTIAL INITIAL IMPACTS DUE TO SOIL EROSION[1]

PROPOSED ALTERNATIVE	TOTAL LENGTH OF ALTERNATIVE (MILES)	MILES OF LOW IMPACT LEVEL AREAS TRAVERSED (PERCENT OF TOTAL LENGTH)	MILES OF MODERATE IMPACT LEVEL AREAS TRAVERSED (PERCENT OF TOTAL LENGTH)	MILES OF HIGH IMPACT LEVEL AREAS TRAVERSED (PERCENT OF TOTAL LENGTH)
Alternative 1	83.1	52.2 (62.8%)	4.9 (5.9%)	26.0 (31.3%)
Alternative 2	60.7	43.7 (71.8%)	1.9 (3.1%)	15.3 (25.1%)
Alternative 2a	62.5	42.7 (68.4%)	2.5 (4.0%)	17.2 (27.6%)
Alternative 3	75.5	48.0 (63.8%)	7.0 (9.3%)	20.2 (26.9%)
No Action	0.0	0.0	0.0	0.0

Notes:

[1] Data from USDA(2008d).

Table 36 shows that Alternative 2 would traverse fewer miles of high impact soil erosion areas than Alternatives 1, 2a and 3. In addition, when comparing the percentage of high impact areas to the total length of the alternatives, the data further show that Alternative 2 would have a lower percentage of high impact soil erosion areas than the other proposed alternatives. The data show that Alternative 1 would traverse more miles and have a higher percentage of high impact soil erosion areas than the other proposed alternatives.

TABLE 37 – SUMMARY OF THE PROPOSED ALTERNATIVE POTENTIAL INITIAL IMPACTS DUE TO CORROSIVE SOILS[1]

PROPOSED ALTERNATIVE	TOTAL LENGTH OF ALTERNATIVE (MILES)	AREAS WITH AVAILABLE DATA (MILES)	LOW IMPACT CORROSIVE SOIL POTENTIAL (MILES)	MODERATE IMPACT CORROSIVE SOIL POTENTIAL (MILES)	HIGH IMPACT CORROSIVE SOIL POTENTIAL (MILES)
Alternative 1	83.1	65.1	17.5	29.3	18.3
Alternative 2	60.7	45.9	5.5	23.0	17.4
Alternative 2a	62.5	46.5	5.5	23.6	17.4
Alternative 3	75.5	71.1	12.8	36.1	22.2
No Action	0.0	0.0	0.0	0.0	0.0

Notes:

[1] Data from USDA (2007b, and 2008a, b, c and d). When multiple soils occur in a single 1/10th mile, the higher potential impact corrosive value is considered.

Table 37 shows that Alternatives 2 and 2a would traverse fewer miles of high impact corrosive soil areas than Alternatives 1 and 3. This is partly due to the shorter length of Alternatives 2 and 2a and the less availability of data. The data show that Alternative 3 would traverse more miles of high impact corrosive soil areas than the other proposed alternatives. This is partly due to the longer distance of Alternative 3, relative to Alternatives 2 and 2a, and the availability of more data for Alternative 3.

TABLE 38 – SUMMARY OF THE PROPOSED ALTERNATIVE POTENTIAL INITIAL IMPACTS DUE TO GROUNDWATER[1]

PROPOSED ALTERNATIVE	TOTAL LENGTH OF ALTERNATIVE (MILES)	AREAS WITH AVAILABLE DATA (MILES)	LOW IMPACT LEVEL AREAS TRAVERSED (MILES)	MODERATE IMPACT LEVEL AREAS TRAVERSED (MILES)	HIGH IMPACT LEVEL AREAS TRAVERSED (MILES)
Alternative 1	83.1	0.6	0.4	0.0	0.2
Alternative 2	60.7	4.1	2.7	0.1	1.3
Alternative 2a	62.5	4.1	2.7	0.1	1.3
Alternative 3	75.5	8.3	2.9	0.0	5.4
No Action	0.0	0.0	0.0	0.0	0.0

Notes:

[1] CDWR, 2008; CGS Seismic Hazards Evaluation Reports.

Table 38 shows that Alternative 1 would traverse fewer miles of high impact groundwater areas than Alternatives 2, 2a and 3. However, Alternative 1 has much less available data than the other proposed alternatives. The data show that Alternative 3 would traverse more miles of high impact groundwater areas than Alternatives 1, 2 and 2a. However, Alternative 3 has much more available data than the other proposed alternatives.

TABLE 39 – SUMMARY OF THE PROPOSED ALTERNATIVE POTENTIAL INITIAL IMPACTS DUE TO DAM FAILURE INUNDATION

PROPOSED ALTERNATIVE	TOTAL LENGTH OF ALTERNATIVE (MILES)	HIGH IMPACT LEVEL INUNDATION AREAS TRAVERSED (MILES)[1]
Alternative 1	83.1	1.5
Alternative 2	60.7	1.4
Alternative 2a	62.5	1.4
Alternative 3	75.5	0.9
No Action	0.0	None

Notes:

[1] Data from County of Los Angeles, 1990; Kern County, 2005; Kern County, 2007.

Table 39 shows that Alternative 3 would traverse fewer miles of high impact level dam failure inundation areas than Alternatives 1, 2, and 2a. The difference in impact areas is due to the geographic extent of the Alternatives relative to mapped dam failure inundation zones.

8.5 NO ACTION ALTERNATIVE

Selection of the No Action Alternative would mean that the BRRTP, as proposed, would not be implemented. As such, potential geologic resources in the affected environment, including highly erosion-sensitive soils and distinctive geologic features, would not be impacted by construction of the proposed Project. However, in the absence of the proposed Project, the purposes and need for the power transmission capabilities that would be met by the Project would not be achieved.

Environmental conditions in the Project study area are expected to naturally change or evolve over time. Therefore, independent of the proposed BRRTP, the potential geologic resources in the Project area would not remain static. If the No Action Alternative is selected, the potential geologic resources preserved in the natural environment by not implementing the Project may remain unchanged over a short geologic time period. However, the potential geologic resources would eventually be affected by long-term, natural geologic processes, independent of the potential impacts associated with the proposed BRRTP.

8.6 CUMULATIVE IMPACTS

8.6.1. Introduction

Cumulative effects are those effects that result from incremental impacts of the proposed action when added to other past, present and reasonably foreseeable future actions. Analysis of cumulative effects places project-specific impacts into a broader context that takes into account the full range of impacts of actions taking place over a given space and time. Cumulative effects may be considered a significant impact to the environment, as degradation of important resources may result from the combined, incremental effects of actions. Cumulative effects may result from individually minor or insignificant actions, which collectively may be considered significant as they accumulate over time and space from one or more actions or sources.

8.6.2. Impacting Factors

Cumulative impacts for geologic resources in the Project study area apply to highly erosion-sensitive soils and distinctive geologic features that may be impacted by the BRRTP. Impacting factors that may affect highly erosion-sensitive soils and highly distinctive geologic features could occur during grading and construction of components of the proposed BRRTP. Erosion of highly sensitive soils could also occur during long-term operation of the BRRTP.

Cumulative impacts related to the major geologic and seismic hazards that may affect the Project apply to surface fault rupture, seismic ground shaking, liquefaction, landslides, soil erosion, settlement, expansive soils, corrosive soils, and groundwater. The impacting factors related to potential geologic and seismic hazards occur due to conditions that may affect the proposed Project from the natural geologic environment.

8.6.3. Impact Area

The geographic areas for considering cumulative impacts related to geologic resources and potential geologic and seismic hazards are the proposed Project study corridors, including the expanded Barren Ridge and proposed new Haskell Canyon switching station locations. This is because geologic conditions and potential resources occur at site-specific locales, and are generally not affected by activities occurring outside the corridors.

8.6.4. Cumulative Projects List – Major Present and Reasonably Foreseeable Future Actions

The cumulative projects list is used to provide a general context for the cumulative effects. This list includes present and reasonably foreseeable future actions in the Project vicinity that have the potential to combine with the Proposed Action or Alternatives. While a distinct impact area for cumulative impacts and specific present and reasonably foreseeable actions is determined individually for each resource area, collectively, the projects listed below represent the major known and anticipated activities that may occur in the general Project area. The Cumulative Projects Map (Figure 8-4) illustrates the location of energy infrastructure and other major projects in reference to the Proposed Action and Alternatives.

As the project list comprises projects in various stages of planning and development, it is likely that some of these projects would be completed as currently proposed while others would not. To be conservative, the cumulative analysis assumes that all projects listed would be built and in operation during the operating lifetime of the proposed Project. The list was developed in consultation with the following agencies:

- USFS – Angeles National Forest (ANF)
- BLM – Ridgecrest Field Office
- BLM – Palm Springs Field Office
- United States Air Force – Edwards Air Force Base
- Kern County – Planning Department
- Los Angeles County – Department of Regional Planning
- City of California City
- City of Lancaster
- City of Palmdale
- City of Santa Clarita
- City of Los Angeles
- City of San Fernando
- LADWP

Transmission Projects

Antelope Transmission Project – Construction of Southern California Edison's (SCE) proposed Antelope Transmission Project is underway and is proceeding in three sequential segments. Construction of Segments 1, 2 and 3A have been completed. Construction of Segment 3B, from Windhub Substation to and including Highwind Substation, has not started and no schedule has been developed by SCE (California Public Utilities – Current Projects).

Segment 1, Antelope – Pardee 500 kV Transmission Line, involved the construction of a new 25.6-mile transmission line between SCE's existing Antelope Substation in the city of Lancaster and SCE's existing Pardee Substation in Santa Clarita, with modifications to and/or expansion of the substations. The line was constructed in an existing SCE 66 kV transmission line right-of-way (ROW) for 23 miles, and within a new ROW for 18 miles. The line is initially energized to 220 kV to serve existing energy demand and can be upgraded to 500 kV to accommodate future needs.

Segment 2, Antelope – Vincent 500 kV Transmission Line, consists of a new 17.8 mile transmission line between the Antelope Substation and SCE's existing Vincent Substation near Acton. Similar to Segment 1, the line would initially be energized at 220 kV and upgraded to meet future needs.

Segment 3, Antelope – Tehachapi Transmission Line, consists of two phases. The first phase, 3A, would involve the construction of a new 26.1-mile 500 kV transmission line between the Antelope Substation and a proposed new substation in the vicinity of the unincorporated community of Mojave (Substation 1). Similar to Segments 1 and 2, this line would be initially energized at 220 kV and upgraded to meet future needs. The second phase, 3B, would involve the construction of a new 9.4-mile 220 kV transmission line from the proposed Substation 1 to a proposed new substation in the Monolith area (Substation 2).

Tehachapi Renewable Transmission Project (TRTP) – SCE is proposing to construct the TRTP, which would involve new and upgraded transmission infrastructure along 173 miles of new and existing rights-of-way, in southern Kern County, portions of Los Angeles County including the ANF, and the southwestern portion of San Bernardino County. Stated objectives for the project include providing the electrical facilities necessary to integrate levels of wind generation in excess of 700 MW and up to 4,500 MW in the Tehachapi Wind Resource Area (California Public Utilities – Current Projects).

The environmental review process for the project is currently underway. Construction began in April 2010 on approved sections. Project construction is estimated to be completed in 2015.

The project is composed of Segments 4 through 11, with Segments 4 through 8 and Segments 10 and 11 being transmission facilities, and Segment 9 being the addition and upgrade of substation facilities. Proposed transmission lines would be constructed primarily within existing rights-of-way. Major project components include:

- Constructing two new single-circuit 220 kV transmission lines within 4 miles of new ROW between the Cottonwood Substation and proposed Whirlwind Substation (Segment 4);
- Constructing a new single-circuit 500 kV transmission line within 16 miles of new ROW between the Antelope Substation and proposed Whirlwind Substation (Segment 4);
- Rebuilding 18 miles of the existing Antelope – Vincent and Antelope – Mesa 220 kV transmission lines to 500 kV standards within existing ROW between the Antelope and Vincent Substations (Segment 5);
- Rebuilding 27 miles of the existing Antelope – Mesa 220 kV transmission line and 5 miles of the existing Rio Hondo – Vincent 220 kV transmission line to 500 kV standards between the Vincent Substation and the southern boundary of the ANF (Segment 6);

- Rebuilding 16 miles of the existing Antelope – Mesa 220 kV transmission line to 500 kV standards between the southern boundary of the ANF and Mesa Substation (Segment 7);
- Rebuilding 33 miles of the existing Chino – Mesa 200 kV transmission line to 500 kV standards between a point 2 miles east of the Mesa Substation and the Mira Loma Substation (Segment 8);
- Rebuilding 7 miles of the existing Chino – Mira Loma No. 1 220 kV transmission line from single-circuit to double-circuit structures (Segment 8);
- Constructing a new 500/220 kV Whirlwind Substation 4 to 5 miles south of the Cottonwood Substation (Segment 9);
- Upgrading the existing Antelope, Vincent, Mesa, Gould, and Mira Loma Substations to accommodate new transmission line construction and system compensation elements (Segment 9);
- Constructing a new single-circuit 500 kV transmission line within 17 miles of new ROW between the Windhub Substation and proposed Whirlwind Substation (Segment 10);
- Rebuilding 19 miles of existing 220 kV transmission line to 500 kV standards in existing ROW between the Vincent and Gould Substations (Segment 11);
- Adding a new 220 kV circuit between the Mesa and Gould Substations on the vacant side of the existing Eagle Rock – Mesa 220 kV transmission line double circuit structures (Segment 11); and
- Installing associated telecommunications infrastructure.

Generation Projects

Numerous wind and solar generation projects are in various stages of planning and development within the Project vicinity. Projects considered include the projects currently undergoing environmental review or projects that have been recently approved. Table 8a below summarizes the major known projects and their current status as of April 2011 (County of Kern Environmental Documents and AV Solar Ranch One).

TABLE 8A. PROPOSED GENERATION PROJECTS IN THE PROJECT VICINITY

Project Name	Project Type	Approximate Generation	Area (acres)	Location	Status
Alta East Wind Project	Wind	300 MW	3,660	Kern County	Application to Kern County deemed complete on Aug. 2010
Alta Wind Energy Center: Alta-Oak Creek Mojave Project	Wind Turbine	800 MW	9,175	Kern County	Approved by Kern County Dec. 2009
Antelope Valley Solar Project	Solar Photovoltaic	650 MW	5,698	Kern County	Draft EIR released April 2011
AV Solar Ranch One	Solar Photovoltaic	230 MW	21,000	Los Angeles County	Final EIR completed Aug. 2010
Avalon Wind Project	Wind	255 MW	10,000	Kern County	Application to Kern County deemed complete on July 2010
Beacon Solar Energy Project	Concentrated Solar	250 MW	2,012	Kern County	Application for Certification approved Aug. 2010
Catalina Renewable Energy Project	Wind Turbine & Solar Photovoltaic	350 MW	7,472	Kern County	Notice of Preparation for a Draft EIR filed Feb. 2011
Clearvista Wind Project	Wind Turbine	40 MW	226	Kern County	Draft EIR released Nov. 2010
Edwards Air Force Base Solar Project	Solar	500 MW	3,288	Kern County	Lease execution anticipated 2012

Project Name	Project Type	Approximate Generation	Area (acres)	Location	Status
Lower West Wind Energy Project	Wind Turbine	14 MW	185	Kern County	Draft EIR released April 2011
Monte Vista Solar Array	Solar Photovoltaic	126 MW	1,040	Kern County	Notice of Preparation for a Draft EIR filed March 2010
Morgan Hills Wind Project	Wind	230 MW	3,604	Kern County	Application submitted Nov. 2010
North Sky River Wind Project	Wind Turbine	326 MW	1,330	Kern County	Notice of Preparation for a Draft EIR filed Nov. 2010
Pacific Wind Energy Project	Wind Turbine	151 MW	8,300	Kern County	Approved by Kern County Oct. 2010
Pahnamid Wind Energy Project	Wind Turbine	411 MW	7,106	Kern County	Notice of Preparation for a Draft EIR filed April 2011
PdV Wind Energy Project	Wind Turbine	300 MW	5,820	Kern County	Approved by Kern County July 2008
Pine Canyon Wind Project	Wind Turbine	150 MW	12,000	Kern County	Preliminary planning
Pine Tree Solar Project	Solar Photovoltaic	10 MW	75	Kern County	Preliminary planning
Pine Tree Wind & Expansion	Wind Turbine	135 MW	n/a	Kern County	Preliminary planning
RE Distributed Solar Project	Solar Photovoltaic	221 MW	1,709	Kern County	Notice of Preparation for a Draft EIR filed Jan. 2011
Ridge Rider Solar Park Project	Solar Photovoltaic	38 MW	475	Kern County	Notice of Preparation of a Draft EIR filed March 2010
Rising Tree Wind Farm	Wind Turbine	234 MW	2,745	Kern County	Notice of Intent to prepare a EIS/EIR filed Jan. 2011
Rosamond Solar Array	Solar Photovoltaic	155 MW	1,177	Kern County	Notice of Preparation of a Draft EIR filed March 2010
Rosamond Solar Project	Solar Photovoltaic	120 MW	960	Kern County	Approved by Kern County Nov. 2010
Sand Canyon Wind Projects	Wind Turbine	40 MW	300	Kern County	Notice of Preparation of a Draft EIR filed Oct. 2010
Willow Springs Solar Array Project	Solar Photovoltaic	160 MW	1,402	Kern County	Notice of Preparation of a Draft EIR filed March 2010
Windstar Wind Energy Project	Wind Turbine	65 MW	1,007	Kern County	Approved by Kern County April 2009

There are also plans in various stages of development to establish additional wind and solar energy projects on BLM land in the Project vicinity. The submission of an application to BLM is a preliminary step in the project planning process, but not all applications ultimately result in successful project development. Below is a list of current applications for wind and solar energy generation projects in the Project vicinity submitted to BLM's Ridgecrest Field Office as of February 2010 (U.S. Department of the Interior, Bureau of Land Management – Renewable Energy).

TABLE 8B. BLM RIDGECREST OFFICE APPLICATIONS FOR WIND AND SOLAR ENERGY GENERATION PROJECTS IN THE PROJECT VICINITY.

Serial Number	Applicant	Date Application Received, ROW Grant Issued, Last Amended Date	Approximate Area (Acres)	Project Type	Location
CACA 46978	Sean Roberts, Renewable Land LLC	7/1/04	528	Pending Wind	Mojave
CACA 47848	Oak Creek Energy	1/11/06	7,349	Pending Wind	Lucchese
CACA 48536	Oak Creek Energy	7/25/06	1,800	Pending Wind	Soledad Mountain Wind Project

Serial Number	Applicant	Date Application Received, ROW Grant Issued, Last Amended Date	Approximate Area (Acres)	Project Type	Location
CACA 48820	First Solar (Formally OptiSolar Inc.)	12/13/08	5,760	Pending Solar	Mojave Area
CACA 49577	Power Partners SW (enXco)	8/10/07	1,816	Pending Wind	Soledad area
CACA 50171	AES SEAWEST INC	7/3/09	120	Pending Wind	Kern County
CACA 50768	Riverside Wind Energy LLC	4/20/09	480	Pending Wind	Gorman
CACA 51016	Advanced Dev Services, Inc	4/30/09	11,174	Pending Wind	Kern County
CACA 51335	Alta Windpower Dev., LLC	7/13/09	584	Pending Wind	Kern County
CACA 51561	Power Partners Southwest	12/11/09	1,160	Pending Wind	Kern County

Other Major Projects

Transportation and Public Facilities

California High Speed Rail – This project proposes a ±700-mile high speed rail line from Sacramento to San Diego. The Statewide Programmatic EIS/EIR was completed in 2005, and the Bay Area to Central Valley High-Speed Train Program EIS/EIR was completed in 2008. Multiple second-tier project-level environmental documents (with preliminary engineering design) are currently underway (California High Speed Rail Authority).

Pacific Pipeline Storm Relocation Project and Access Road Repairs – Pacific Pipeline is proposing to relocate several miles of crude oil pipeline to more stable ground within the ANF. Project implementation was expected in November 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Antelope Valley Water Bank Project – This project proposes to develop facilities to store and recharge imported surface water and associated delivery and distribution pipelines. The 13,440-acre facility area would be bounded by the Kern/Los Angeles County border line (also known as Avenue A) to the south and Rosamond Boulevard to the north, and between 170th Street West and 100th Street West in unincorporated Kern County (U.S. Department of the Interior, Bureau of Reclamation – Mid-Pacific Region).

Soledad Canyon Cemex Project – The Soledad Canyon Cemex project would be a 56-million-ton sand and gravel mining project in the Soledad Canyon area. The BLM approved the project with mitigating measures in 2000, and the Interior Board of Land Appeals affirmed that decision in 2002. A City of Santa Clarita challenge to the US Supreme Court was denied in 2006. This project is pending development with ongoing challenges and delays (Cemex United States).

Community Development

Centennial, California – The proposed project site consists of 12,000 acres located one mile east of Interstate 5 (I-5) and adjacent to State Highway 138 in Los Angeles County. The project would include a specific plan and subdivision entitlements (i.e., tract maps and conditional use permits) for a master planned community. The specific plan proposes a maximum of 23,000 dwelling units and 14 million total square feet of non-residential development of employment areas (12,233,390 square feet) and retail serving centers (1,986,336 square feet), anticipated to be built over approximately 20 years, with build-out expected in 2030. If the project is approved by Los Angeles County, it is estimated that the non-residential development may generate approximately 31,000 jobs. The draft Specific Plan for the unincorporated community of Centennial was submitted to Los Angeles County in February 2003 and is currently being reviewed by the county (Centennial, California).

Maintenance and Landscape Management Projects

Bouquet Canyon Road Realignment – Los Angeles County Department of Public Works is proposing to straighten some sections of Bouquet Canyon Road and to raise the road surface by approximately nine feet. A Memorandum of Understanding between ANF and Los Angeles County is currently under development to initiate the project (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

San Francisquito Road Rehabilitation and Sediment Disposal Site – Los Angeles County Department of Public Works is proposing a road realignment and new bridge along San Francisquito Road within the ANF and to use eight acres of Forest land as a spoils site in support of construction activities. Public Scoping began in June 2007, and a decision was expected in September 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Old Ridge Route Storm Damage Repair – USFS is proposing to repair and provide maintenance to seven storm-damaged locations along the Old Ridge Route in ANF. A decision on the project is expected in late 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Livestock Grazing Allotments – BLM currently authorizes both cattle and sheep grazing on 11 grazing allotments in and around the project area. The livestock are authorized with 10 year permits/leases and yearly authorizations. These allotments encompass over one half million acres of BLM-managed lands. The number of livestock grazed each year depends upon weather conditions. The majority of the livestock are sheep. The number of sheep average around thirty thousand head. Three of the allotments support several thousand head of cattle (Harris 2010).

Tule Ridge/South Portal Fuels Reduction Project – USFS proposes fuels reduction and re-establishment of a fuel break to provide protection to unincorporated community of Green Valley. The project would also enhance wildlife for mammals and birds (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Jupiter Fuelbreak Project – USFS proposes to re-establish an existing fuel break that begins southwest of the unincorporated community of Green Valley and travels east, bisecting Jupiter Mountain, before heading south to Bouquet Reservoir.

Santa Clara/Mojave River Rangers District Plantation Maintenance Project – The proposed project would consist of vegetation maintenance at 13 plantations located within the ANF in order to reduce wildfire risk, and improve wildlife habitat and the vitality of individual remaining trees. Proposed actions include removal of dead trees, thinning of live trees, pruning, removing weeds, and planting for reforestation where necessary. This action was approved by the District Ranger in January 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Lake Hughes Plantation Restoration Project – The proposed project would restore unauthorized off-highway vehicle trails at the Christian and Taylor Plantations located within the ANF in order to reduce soil erosion, the spread of weeds, destruction of native plants, soil compaction, and wildlife habitat loss. Proposed actions include recontouring and decompacting soils, reseeding with native species, and reinforcing check dams. The project was approved by the District Ranger in 2009 and scheduled for implementation in January 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Bouquet and San Francisquito Habitat Improvement Project – The project proposes invasive species removal in Bouquet and San Francisquito Canyons (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Local Projects

In conjunction with the major projects listed above, a summary of local foreseeable projects within the study area that could contribute to cumulative effects are summarized in the table below. These proposed projects were gathered from applications to the planning departments of the various jurisdictions and have been categorized by project type.

TABLE 8C. PROPOSED LOCAL PROJECTS IN THE PROJECT VICINITY.

	Kern County	Los Angeles County[1]	City of California City	City of Palmdale[2]	City of Lancaster	City of Santa Clarita	City of Los Angeles	City of San Fernando
Single Family Residential (may include multiple units)	1	96	0	14	93	10	2	2
Multi Family Residential (may include multiple units)	28	9	0	9	2	1	2	1
Schools	2	2	0	9	2	0	0	0
Religious Uses	10	7	0	13	0	0	1	1
Recreational Facilities	7	5	0	7	1	0	0	1
Public Facilities – police, fire, library, correctional	2	5	0	4	0	0	0	0
Commercial/ Office Development	40	33	0	96	6	21	2	7
Hotels/Motels	1	0	0	9	2	1	1	2
Medical/Care Facilities	4	6	0	16	0	1	0	1
Industrial Facilities	20	0	0	17	1	6	2	2
Mining Operations	15	0	0	4	0	0	0	0
RV Facilities	2	0	0	0	0	0	0	0
Animal Facilities	8	6	0	1	0	0	0	0
Aviation Facilities	2	0	0	0	0	0	0	0
Non-Commercial Energy Facilities	1	2	0	0	0	0	0	0

[1] Projects listed for Los Angeles County include all projects that could contribute to cumulative effects within the following County Districts: Antelope Valley West, Bouquet Canyon, Castaic Canyon, Chatsworth, Lancaster, Leona Valley, Mount Gleason, Newhall, North Palmdale, Palmdale, Quartz Hill, Sand Canyon, Soledad. Some identified projects included may be outside of the study area.

[2] Projects listed for the City of Palmdale include all projects that could contribute to cumulative effects within the City. Some identified projects included may be outside of the study area.

8.6.5. Cumulative Impacts Summary

Past and ongoing development within the proposed BRRTP area has resulted in alterations to the natural geologic conditions. Past, existing and future projects could contribute cumulative impacts on the geologic resources within the study area by creating erosion of highly sensitive soils and alteration of distinctive geologic features. These potential impacts to geologic resources would be limited to areas within and adjacent to the boundaries of individual projects, and such impacts would have to occur in similar locations within the boundaries of the proposed BRRTP. However, construction of the proposed BRRTP would preclude other projects from being implemented concurrently in the same location. Therefore, proposed Project impacts related to highly erosion-sensitive soils and highly distinctive geologic features would not have the potential to combine with similar impacts from other projects and would not have cumulative impacts.

The major geologic and seismic impacts that may affect the proposed BRRTP (surface fault rupture, seismic ground shaking, liquefaction, landslides, settlement, expansive soils, corrosive soils, and groundwater) are related to outside effects from the natural environment that may impact the Project, and are not related to impacts from other past, present, or future projects in the study area. The impacts related to surface fault rupture, ground shaking, liquefaction and earthquake-induced landslides are related to earthquakes and would not be due to other projects in the BRRTP impact area. The effects of soil erosion that may impact the Project components are due to the nature of the earth materials, steepness of the terrain and other natural factors that are not related to other projects. Potential settlement, expansive soils and corrosive soils are also related to the inherent natural properties of soils underlying the Project components, and would not be due to effects from other projects. Therefore, the impacts to the BRRTP related to potential geologic and seismic hazards are not considered to have cumulative impacts, since they are not due to other past, present or future projects within the impact area.

1.0 230 KV DOUBLE-CIRCUIT TRANSMISSION LINE

1.1 CONSTRUCTION SEQUENCE

Construction of a transmission line involves the following general sequence of events: surveying the centerline; identifying and constructing access roads; clearing right-of-way and tower sites (including construction yards and batch plants); installing foundations; assembling and erecting the towers; clearing, pulling, tensioning, and splicing sites; installing ground wires and conductors; installing counterpoise; switching station tie in; and cleanup and site reclamation. Various phases of construction would occur at different locations throughout the construction process for the Barren Ridge Renewable Transmission Project (BRRTP). This would require several contractors operating at the same time and in different locations.

The following section describes the construction components necessary for the assembly and installation of the proposed double-circuit transmission line. The description of transmission line construction sequencing and estimates for construction sites would also be relevant for the additional transmission line construction activities associated with the installation of the Castaic-Haskell Canyon #4 circuit on existing structures, and the reconductoring of the Barren Ridge – Rinaldi (BR-RIN) transmission line between the Barren Ridge Switching Station and the Rinaldi Substation.

1.1.1 Surveying Activities

The Los Angeles Department of Water and Power (LADWP) must first obtain survey permits for the portion of the Project crossing federal lands managed by the U.S. Department of Agriculture, Forest Service (USFS) and the U.S. Department of the Interior, Bureau of Land Management (BLM), and rights-of-entry for private lands. This would include the issuance of a 50-year term Special Use Permit to LADWP by the USFS and a 30-year term (renewable) Right-of-Way Grant issued by the BLM. For survey on affected private lands, LADWP would need to negotiate rights-of-entry with the local landowners. Once survey permits are obtained, construction survey work would consist of locating the centerline, tower center hubs, ROW boundaries, and tower access roads, some of which would be located outside of the ROW boundaries. Whenever possible, location of the ROW and Project facilities would be laid out to avoid identified sensitive resources. All of these activities would begin approximately one year prior to the start of construction. Cultural resources and necessary additional threatened and endangered species intensive surveys would be conducted once the survey of the centerline and access roads is completed and clearly marked.

Necessary pre-construction geotechnical investigations would include geological field mapping of each tower site, and borings by drill rig for soil sampling and bedrock corings to determine soil densities and bedrock strength. Test locations would include angle points between the Barren Ridge Switching Station and the Angeles National Forest (ANF), and five to ten locations along the selected alignment within the ANF. Seismic analysis of tower sites for slope stability would also be necessary in mountainous areas of the ANF. Existing roads would be used as much as possible, but some new roads could be required.

1.1.2 Preconstruction Weed Removal

LADWP/ANF/BLM shall prepare and implement a comprehensive, adaptive Weed Control Plan on NFS/BLM lands for pre-construction and construction invasive weed abatement. A pre-construction weed inventory shall be conducted by surveying all areas subject to ground-disturbing activity, including, but not limited to, tower pad preparation and construction areas, tower removal sites, pulling and tensioning

sites, assembly yards, and areas subject to grading for new or improved access and spur roads. In areas subject to ground disturbance, weed infestations shall be treated prior to construction according to control methods and practices for invasive weed populations designed in consultation with the USFS/BLM. The Weed Control Plan shall be updated and utilized for eradication and monitoring post construction. Weed control treatments shall include all legally permitted herbicide, manual, and mechanical methods applied with the authorization of the USFS/BLM. The application of herbicides shall be in compliance with all state and federal laws and regulations under the prescription of a Pest Control Advisor (PCA), where concurrence has been provided by the USFS/BLM, and implemented by a Licensed Qualified Applicator. Herbicides shall not be applied during or within 24 hours of a scheduled rain event. Herbicides shall not be used within Riparian Conservation Areas (RCAs) on the ANF without approval of the USFS. In riparian areas, only water-safe herbicides shall be used. Herbicides shall not be applied when wind velocities exceed six miles per hour. Where manual and/or mechanical methods are used, disposal of the plant debris will follow the regulations set by the USFS/BLM. The timing of the weed control treatment shall be determined for each plant species in consultation with the USFS/BLM (on NFS/BLM lands, respectively) with the goal of controlling populations before they start producing seeds.

1.1.3 Construction of Access Roads

The construction, operation, and maintenance of the proposed transmission line would require that heavy vehicles access tower sites along the right-of-way. Where new access roads are required, they would be constructed to support the weight of these vehicles and would typically be 16 feet wide, consisting of a 14-foot driving surface with a side drainage system between one and two feet in width. Permanent roads would be constructed where necessary for operation or maintenance, or where it is required by the landowner or land managing agency. Road standards would be addressed specifically in the Construction, Operation, and Maintenance Plan (COM Plan) and the Plan of Development (POD) during the engineering phase of the Project, and prior to a Notice to Proceed from the USFS and BLM.

Dependent upon final design and mitigation, some temporary access roads may be constructed as part of the Project. These would typically be 16 foot wide roads, but would typically have no improved ditch drainage systems. Most temporary roads would be constructed by crushing vegetation. In some areas, material and topsoil from the temporary roads would be bladed to one or both sides to facilitate rehabilitation. Following construction, bladed material can be re-spread across the disturbed road section. Seeds and roots contained within the re-spread topsoil layer normally provide a natural source for new growth.

Existing paved and unpaved highways and roads would be used where possible. Roads along existing utility corridors would also be used where possible to minimize new access road construction. In locations where existing roads can be used that are located in close proximity to the proposed centerline of the transmission line, only spur roads to the tower sites would be required. New access roads and spur roads would likely be constructed into the right-of-way where existing roads do not exist. Table 1 lists the estimated ground disturbance of access and spur roads based on terrain.

TABLE 1. ACCESS AND SPUR ROAD GROUND DISTURBANCE ESTIMATES

Ground Disturbance Categories	Access Roads		Spur Roads (average width 16 feet)	
	Average Miles of Roads Per Mile of Transmission Line	Average Acres of Disturbance Per Mile of Transmission Line*	Average Miles of Roads Per Mile of Transmission Line	Average Acres of Disturbance Per Mile of Transmission Line
1. Existing roads or agricultural land; no widening anticipated	n/a	n/a	0.3	0.6
2. Existing 8 ft wide roads that require an additional 8 ft of widening	1.0 to 2.5	Permanent 0.9 to 2.4	0.3	0.6
3. Construct new road on flat terrain (0-10%)	1.0 to 2.5	Permanent 1.9 to 4.8	0.3	0.6
4. Construct new road on sloping terrain (10-20%)[1]	2.5 to 4.0	Temporary 7.3 to 11.6 Permanent 4.8 to 7.7	0.5	1.0
5. Construct new road on steep terrain (20-30%)[1, 2]	4.0 to 6.0	Temporary 23.3 to 34.9 Permanent 7.7 to 11.6	0.8	1.6
6. Construct road on very steep terrain (greater than 30%)[1, 2]	6.0 to 8.0	Temporary 69.8 to 93.1 Permanent 11.6 to 15.5	1.0	1.9

[1] After construction of the transmission line, all access roads in Categories 4 through 6 would be restored back to 16 feet wide.
[2] On steep terrain (approximately 25% or higher) with limited access on the Angeles National Forest, the USFS may require Helicopter Mitigation.

Wherever possible, roads would be built at right angles to streams and washes. Culverts or other drainage structures would be installed as necessary across drainages, but the roads would usually follow the natural grade. In addition, road construction would include dust-control and erosion control measures in sensitive areas. All existing roads would be left in a condition equal to or better than their condition prior to the construction of the transmission line without changing their service level. Gates would be installed where required at fenced property lines to restrict general vehicular access from or to the right-of-way. Where identified within the environmental studies for mitigation purposes, access roads may be excluded or limited within specific sensitive areas, such as Riparian Conservation Areas (RCAs) on the Angeles National Forest.

1.1.4 Clearing Right-of-Way

The clearing of some natural vegetation may be required. However, selective clearing would be performed only when necessary to provide for surveying, electrical safety clearances, line reliability, and maintenance. Trimming or removal of mature vegetation, under or near the conductors, would be done to provide adequate electrical clearance as required by the National Electrical Safety Code, the North American Electrical Reliability Corporation, and California Public Utilities Commission General Order 95 standards.

Trees that could fall onto the lines or affect lines during wind-induced line swing would be removed. Normal clearing procedures are to top or remove large trees and not disturb smaller trees. Where there is a direct conflict between trees and clearance standards, the removal of trees would be jointly reviewed and agreed upon between LADWP and the owners or managers of the property. Rights-of-way would not be chemically treated unless necessary to comply with requirements of a permitting agency. On National Forest System (NFS) lands, approved herbicides would be utilized within the Project area on select invasive plant species. Invasive plant surveys and control would continue for the life of the Project.

1.1.5 Tower Site Clearing

After access roads are developed, preparation of individual structure sites would be required to install the structures. At tower locations, work areas of up to 200 feet squared in flat terrain and up to 200 by 250 feet in areas with slopes greater than eight percent may be needed. Within the work areas, at some tower locations, a level cleared area (pad) may be necessary to complete the construction of the towers. However, many tower sites would be considerably smaller depending on the size of the tower, the terrain, resource considerations, and whether helicopter construction was used, among other factors. The work area would be required for the location of tower footings, assembly of the tower, and the necessary crane maneuvers. Vegetation would be mostly crushed, and cleared only when necessary. All pads not needed for normal transmission line maintenance would be graded to blend as near as possible with the natural contours, and revegetated where required by a permitting agency. See Table 2 for tower specifications and Table 5 for estimated temporary and permanent ground disturbance associated with the double-circuit steel lattice towers.

TABLE 2. DOUBLE-CIRCUIT STEEL LATTICE TOWER SPECIFICATIONS

Tower Placement Details	Specifications	
	Categories 1 through 3 Flat (0 – 10% slope)	Categories 4 through 6 Mountainous (10 – 30% slope)
Towers per mile	±5	±5
Average span length	1,100 ft.	1,000 ft.
Average height Ground to lowest attachment	115 ft.	105 ft.
Upper body height	52 ft.	52 ft.
Overall tower height	167 ft.	157 ft.
Typical range of heights of new towers	120 – 195 ft.	110 – 185 ft.

1.1.6 Staging Areas and Batch Plants

It is anticipated that one or two construction yards or staging areas would be required for materials storage, construction equipment, construction vehicles, and temporary construction offices. Staging areas would be approximately five acres in size, and located centrally or near each end of the transmission line route. The staging areas would be located on previously disturbed private land and would be level and surfaced with crushed aggregate base. The LADWP would negotiate with landowners for specific locations of the staging areas.

Concrete for use in constructing foundations would be dispensed from a portable concrete batch plant located at approximately 15 mile intervals. A rubber-tired flatbed truck and tractor would be used to relocate each plant along the right-of-way. Commercial ready-mix concrete would be used when access to tower construction sites is economically feasible.

The construction yards and batch plants would be located on private land and serve as field offices, reporting locations for workers, parking space for vehicles and equipment, sites for material storage, and stations for equipment maintenance. Facilities would be fenced and their gates locked. Security guards would be stationed where needed. See Table 3 for estimated ground disturbance associated with the staging sites and batch plants.

TABLE 3. STAGING SITES AND BATCH PLANT GROUND DISTURBANCE ESTIMATES

Disturbance Description	Categories 1 through 3 Flat (0 – 10% slope)*	
	Maximum Estimated Disturbance Dimension per site	**Average Disturbance**
Material staging sites (2 sites)	400 x 540 ft. (5 acres)	N/A
Concrete batch plants (3 sites maximum)	2 acres, 30 mile haul distance	0.2 acre per mile
Total Average Disturbance	**0.2 acre per mile**	

*Material staging sites and concrete batch plants would not be built on terrain above 10% slope.

1.1.7 Foundation Installation

Tower foundations for the lattice structures would consist of drilled concrete piers. The foundation process would start with the boring of four holes for each lattice structure or one hole for each TSP. The holes would be bored using truck- or track-mounted excavators with various diameter augers to match diameter and depth requirements of the foundation sizes.

For a typical suspension lattice tower, each hole would typically be four feet in diameter and 25 feet deep, depending on soil conditions. For the larger angle or dead-end structures, foundations could be up to 30 or more feet deep, depending on soil conditions. Each foundation would extend above the ground line between six inches and four feet. In extremely sandy areas, soil stabilization by water or a gelling agent may be used prior to excavation. Refer to Figure 1 and Figure 2 for typical foundation details for double-circuit towers.

Following excavation of the foundation holes, each footing would be constructed by placing formwork, reinforcing steel and a tower stub into the foundation hole, positioning the stub, and encasing it in concrete. Reinforcing steel cages would be assembled at laydown yards and delivered to each structure location by flatbed truck. Spoil material would be spread around the tower site and used for fill where suitable. The foundation excavation and installation would require access to the site by a power auger or drill, a crane, material trucks, and ready-mix trucks. Typical suspension structures would require approximately 25 to 40 cubic yards of concrete and dead-end structures would require approximately 120 cubic yards of concrete.

1.1.8 Tower Assembly and Installation

The size of the work areas for structures (assembly and installation sites) would be approximately 40,000 to 50,000 square feet (1 acre = 43,560 ft^2) depending on terrain. The location of these sites has not yet been determined, but exact locations would be identified within the COM Plan and POD prior to a Notice to Proceed from the agencies. Lattice towers would be assembled at each site, installed and bolted to the foundations. Bundles of steel members and associated parts would be transported to each tower site by truck. Steel members would be assembled into subsections of convenient size and weight on the ground. Assembly would be facilitated with a small rough-terrain crane. The assembled subsections would be erected into place by a large crane and then fastened together in the air to form a complete tower. See Figure 3 for an illustration of typical tower assembly and installation activities.

FIGURE 3. TYPICAL TOWER ASSEMBLY AND INSTALLATION ACTIVITIES

1.1.9 Conductor Installation

After the towers are erected, insulators, hardware, and stringing sheaves would be delivered to each tower site. The towers would be rigged with insulator strings and stringing sheaves at each ground wire and conductor position. Sheaves are rollers, temporarily attached to the lower end of the insulators that allow the conductor to be pulled, or "strung," along the line.

For public protection during wire installation, temporary guard structures would be built next to highways, railroads, power lines, structures, and other major obstacles. Guard structures would consist of

H-frame poles placed on either side of an obstacle. These structures would prevent ground wire, conductor, or equipment from falling on an obstacle. Equipment for installing guard structures would include augers, line trucks, pole trailers, and cranes. A guard structure would be anticipated to be necessary every five miles. The amount of ground disturbance would typically be 200 feet by 300 feet. The guard structures would be left in place until conductors and ground wires were strung, tensioned and clipped; this time frame would be approximately three weeks or longer depending on conditions. Guard structures may not be necessary for small roads. In such cases, other safety measures, such as barriers, flagmen, or other traffic control, would be used.

Pilot lines would be pulled (strung) from tower to tower by a helicopter and threaded through the stringing sheaves at each tower. The pilot line can be used to pull in the ground wire, but is used to pull in a larger-diameter, stronger pulling line for the conductor. The larger-diameter, stronger line—pulling line—would be attached to the conductors to pull them onto towers. This process would be repeated until the ground wire or conductor is pulled through all sheaves. Bundled conductors would be pulled together with the assistance of a running board. The running board attaches the bundled conductor to the pulling line.

Ground wire and conductors would be strung using powered pulling equipment at one end and powered braking or tensioning equipment at the other end of a conductor segment as shown on Figure 4. Sites for tensioning equipment and pulling equipment would be approximately 2.5 miles apart.

THREE DRUM PULLER
CLEAN-UP & REHABILITATION
TENSIONER
REELS OF CONDUCTOR
DISCLAIMER: FIGURE NOT TO SCALE

To the greatest extent practical, pulling and tensioning sites would be located within the transmission ROW. However, some pulling and tensioning sites may occur outside the ROW. The tensioning and pulling sites could be as large as 200 feet by 500 feet, however they would be limited in size depending on each specific location and what is reasonable for safe construction practices. The size of each site would be limited as much as possible and would be designed in coordination with the responsible property owner or land management agency. Depending on topography, some grading may be required at pulling and tensioning sites to create level pads for equipment. Tensioners, line trucks, wire trailers, and tractors needed for stringing and anchoring the ground wire or conductor would be located at the tensioning sites. A puller, line trucks, sag cat and tractors would be needed for pulling and temporarily anchoring the ground wire and conductor. Table 5 includes ground disturbance estimates for conductor installation (helicopter fly yards, portable helicopter landing pads, pulling and stringing sites, and sleeving and stringing operations).

After installing the conductor ground wire or fiber optic shield wire, sagging, clipping and dead-ending activities, terminating the conductors at dead-end structures, would be performed. This process would involve adjusting the position of the conductors and shield wires, removing stringing sheaves, and permanently attaching the conductor to the insulators with specialized hardware.

1.1.10 Counterpoise Installation and Grounding Practices

Part of standard construction practice prior to wire installation would involve measuring the resistance of tower footings and installation of counterpoise (grounds) as needed. To determine if a tower would require counterpoise, ground resistance measurements would be taken at towers sites after the installation of the foundations and structures. The measurements would be evaluated to determine the numbers and locations of structures requiring counterpoise. If the resistance to remote earth for each transmission tower is greater than 10 ohms, counterpoise (grounds) would be installed to lower the resistance to 10 ohms or less. Counterpoise would consist of a bare copper-clad or galvanized steel cable buried a minimum of 12 inches deep, extending horizontally from one or more tower legs for approximately 200 feet. Typical counterpoise installation would include two installations per structure on opposite tower legs. Four installations per tower could be required in certain circumstances.

In addition to counterpoise installation, standard grounding practices during construction would include both temporary and permanent grounding of equipment and structures, such as fences or pipelines, as necessary to reduce any potential magnetically induced voltages to harmless levels. Such practices could include electrical isolation of equipment or structures and the installation of grounding wires.

1.1.11 Switching Station Tie-in

At the proposed Haskell Canyon Switching Station, the transmission lines would be connected into and out of the switching station through dedicated station structures within the switching station, commonly referred to as "bus."

1.2 UPKEEP OF CONSTRUCTION SITES

Construction sites, material storage yards, and access roads would be kept in an orderly condition throughout the construction period. Refuse and trash would be removed from the sites and disposed of in an approved manner. Oils and fuels would not be dumped along the line. Oils or chemicals would be hauled to a disposal facility authorized to accept such materials. No open burning of construction trash would occur without agency approval.

Microtrash would be cleaned daily from all work areas within known California condor habitat. Microtrash is a term used to describe small bits of debris like bottle caps, rags, screws, bolts, wires, glass, and other materials found in condor habitat.

1.3 HAZARDOUS MATERIALS WITHIN THE PROJECT AREA

Petroleum products such as gasoline, diesel fuel, helicopter fuel, crankcase oil, lubricants, and cleaning solvents would be present within the Project area during construction. These products would be used to fuel, lubricate, and clean vehicles and equipment. These products would be containerized by fuel trucks or by approved containers. When not in use, hazardous materials would be properly stored to prevent drainage or accidents.

Hazardous materials would not be drained onto the ground or into streams or drainage areas. Totally enclosed containment shall be provided for all trash. All construction waste including trash and litter, garbage, other solid waste, petroleum products, and other potentially hazardous materials would be removed to a disposal facility authorized to accept such materials.

All construction, operation, and maintenance activities would comply with all applicable federal, state, and local laws and regulations regarding the use of hazardous substances.

The construction or maintenance crew foreman would insure that all applicable laws are obeyed. In addition, an on-site inspector would be present during construction to make sure that all hazardous materials are used and stored properly. A health and safety plan would be developed as part of the COM Plan and POD during the engineering and preconstruction phase of the Project.

1.4 SITE RECLAMATION

The ROW, including temporary construction sites, and any temporary ground disturbance outside of the ROW that may have been caused during or due to the construction of the Project (e.g., temporary access roads, staging sites, assembly yards) would be restored as required by the property owner or land management agency. All practical means would be used to restore the land to its original contour and to restore natural drainage patterns along the ROW. Because revegetation would be difficult in many areas of the Project where precipitation is minimal, it would be important to minimize disturbance during construction. All practical means would be used to increase the chances of vegetation reestablishment in disturbed areas.

The total construction period would be approximately two years. The COM Plan that would be completed during the engineering and preconstruction phase of the Project would address specific site reclamation of all disturbed areas.

1.5 FIRE PROTECTION

A Fire Management Plan would be developed for the Project and all applicable fire laws and regulations would be observed during the construction period. All personnel would be advised of their responsibilities under the applicable fire laws and regulations, including taking practical measures to report and suppress fires.

1.6 CONSTRUCTION MONITORING

An approved compliance program would be developed to address mitigation requirements associated with the avoidance of sensitive plant and animal species, cultural sites, or other sensitive features located

within or adjacent to the Project. Prior to construction, these measures will be described in detail and included in the POD.

1.7 THREE-CIRCUIT TOWER MITIGATION

A temporary transmission line would be constructed to keep the BR-RIN circuit energized during construction of the three-circuit towers. After the temporary line is constructed, the existing BR-RIN single-circuit towers would be removed to allow the new three-circuit towers to be constructed within the existing ROW. Once construction of the three-circuit towers is completed, the temporary transmission line would be removed.

The temporary transmission line would be 7.5 miles long and would consist of wood and steel single poles with an average height of 95 feet, a 3-foot by 3-foot footprint, and an average of eight poles per mile. Construction would occur within a temporary 80- to 100-foot ROW. Refer to Table 4 for specifications and to Table 5 for ground disturbance estimates. The majority of the temporary transmission line would be constructed along San Francisquito Road. Portions would also be constructed along Elizabeth Lake Road and Johnson Road. Pole placement would be adjacent to public roadways wherever possible. If necessary, temporary ROW on private property would be needed where poles could not be placed within public road ROW. The majority of poles would be direct-embedded when set in place and would not require a permanent foundation. Where additional strength is necessary at larger angle points, steel poles would be required, which could require an excavation approximately 6 feet in diameter by 20 feet deep to accommodate the concrete pier foundation that would be cast in place. Once all the poles have been constructed and the conductor installed, the existing BR-RIN circuit would be connected into the temporary line and energized. The construction would require establishment of a staging area, work areas around poles, and pull and tension sites. Access to pole sites and pull and tension sites would be from the adjacent roadways.

Approximately seven miles of the existing BR-RIN single-circuit towers would be removed, with existing ROW utilized to access the existing towers. The new three-circuit towers would be placed within the existing ROW, utilizing existing access roads. Helicopter Mitigation, as described in this section below, would be applied in steeper terrain crossing the Angeles National Forest if additional access is required. If additional access roads, considered to be longer than 300 feet, are necessary, specific locations and construction method (either helicopter or conventional) would be coordinated with the USFS. The new three-circuit tower would require a 25-foot by 30-foot structure footprint and an average of seven structures per mile; the average structure height would be 170 feet, with a maximum tower-to-tower span length of 780 feet. Structures would be installed in the same locations as the existing BR-RIN structures within the limits of standard tower design. The construction process for the new three-circuit towers would be the same as the double-circuit towers discussed above. After completion of construction of the three-circuit towers, the temporary transmission line would be removed and all temporary staging and work area land disturbances would be restored as close to previous conditions as possible and revegetated as required. Restoration practices would be consistent with Section 1.11 Decommissioning of Transmission Lines.

TABLE 4. THREE-CIRCUIT TOWER SPECIFICATIONS

Tower Placement Details	Specifications	
	Triple-Circuit	Temporary Transmission Line
ROW acquisition	None (within existing)	80-100 ft
Structures per Mile	7	8
Average span length	750 ft	650 ft

Tower Placement Details	**Specifications**	
	Triple-Circuit	**Temporary Transmission Line**
Average height (ft)		
Ground to lowest attachment	120	60
Upper body height	50	45
Overall tower height	170	105
Typical range of heights of new towers	150 - 180 ft.	95 - 105 ft.

1.8 HELICOPTER MITIGATION

The following sites and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas and associated temporary access roads, tower structure vegetation clearing, guard structures at major crossings, and access road pullouts. Refer to Table 5 for ground disturbance estimates for the Helicopter Mitigation.

The transmission line materials (tower steel, conductor reels, structure hardware, etc.) would be delivered by truck to the helicopter fly yards/staging areas. Vegetation clearing may be required at these sites to ensure safe working conditions. The fly yards/staging areas would serve as helicopter support yards for fueling and maintenance, as well as for the transport of materials and personnel. Towers may also be assembled in sections at these yards prior to delivery to the tower sites. Heavy lift helicopters would then fly the towers from the yards to the tower sites.

Portable landing pads would be located at each tower site. These pads would allow helicopters to load and unload personnel, tools, and equipment necessary for construction of foundations and assembly of tower structures. Helicopter-constructed towers that would not be in close proximity to existing access roads would utilize micropile foundations. For each tower leg, micropile foundations would use a group of three to eight 6- to 9-inch diameter casings that would be drilled and grouted into the ground. The exposed portion of the pile group would be encased in a reinforced concrete cap from the top of the casings to a depth anywhere from one to eight feet below the ground surface, depending on the terrain. Figure 5 illustrates the plan view and sections of a micropile foundation.

SUPPORT

Conductor installation would proceed as for double-circuit tower installation. The equipment necessary for conductor installation would be large, heavy construction equipment that could only be brought in by truck. Some NFS roads could need maintenance or improvement to allow pulling and tensioning, but no new access or spur roads would be created for conductor installation on the helicopter-constructed towers.

THIS PAGE INTENTIONALLY LEFT BLANK

TABLE 5 GROUND DISTURBANCE ESTIMATES FOR THE PROPOSED 230 KV DOUBLE-CIRCUIT TRANSMISSION LINE

Disturbance Description	Double-Circuit Steel Lattice Towers with Helicopter Stringing of Conductors		Three-Circuit Tower Mitigation (Three-Circuit Steel Lattice Towers with Helicopter Stringing of Conductors)				Helicopter Mitigation (Steel Lattice Towers with Helicopter Installation of Towers and Conductors)	
			Three-Circuit		Temporary Transmission Line

THIS PAGE INTENTIONALLY LEFT BLANK

1.9 OPERATION OF TRANSMISSION LINES

The nominal voltage for the BRRTP transmission line would be 230 kV AC. There may be minor variations of up to five percent above the nominal level depending upon load flow.

1.9.1 Permitted Uses

After the transmission line has been energized, land uses that are compatible with safety regulations (such as agriculture and grazing) would be permitted in and adjacent to the right-of-way. Incompatible land uses within the right-of-way include construction and maintenance of inhabited dwellings, and any use requiring changes in surface elevation that would affect electrical clearances of existing or planned facilities.

Land uses on public lands that comply with local regulations would be permitted adjacent to or within the ROW, with require approval from the appropriate agency. Permission to use the ROW on private lands would have to be obtained from the utility owning the transmission line.

1.9.2 Safety

Safety is a primary concern in the design of this 230 kV transmission line. The AC transmission line would be protected with power circuit breakers and related line relay protection equipment. If conductor failure occurs, power would be automatically removed from the line. Lightning protection would be provided by overhead ground wires along the line. Electrical equipment and fencing at the switching station would be grounded. All fences, metal gates, pipelines, and other metal components that cross or are within the transmission line ROW would be grounded to prevent electrical shock. If applicable, grounding outside of the ROW may also occur.

1.10 MAINTENANCE OF TRANSMISSION LINES

The 230 kV transmission line would be inspected several times annually by both ground and air patrols. Maintenance would be performed as needed. When access is required for non-emergency maintenance and repairs, LADWP would adhere to the same precautions and procedures that were taken during the original construction.

Emergency maintenance would involve prompt movement of repair crews to repair or replace any damaged equipment or infrastructure. Crews would be instructed to protect crops, plants, wildlife, and other resources of significance. Restoration procedures following completion of repair work would be those prescribed for project implementation construction. The comfort and safety of local residents would be provided for by limiting noise, dust, and the danger caused by maintenance vehicle traffic. Details would be provided in the COM Plan and POD prior to line construction.

1.10.1 Vegetation Management

Vegetation management along the transmission line ROW would be required by the North American Reliability Council (NERC). In compliance with the NERC's Standard FAC-003-l, LADWP would prepare a Vegetation Management Plan for the BRRTP. The Vegetation Management Plan would be included in the COM Plan to be completed prior to the issuance of a Notice to Proceed from the USFS and BLM. Vegetation management would consist of routine tree trimming to maintain the required minimum 10-foot clearance from conductors to vegetation (California Public Resources Code [PRC] 4293); clearance of flammable brush vegetation within a 10-foot radius around the base of transmission line towers in accordance with California PRC 4292; and clearance immediately adjacent to access roads to permit adequate access to the facilities.

1.10.2 Access Road Maintenance

Ongoing access road maintenance would be conducted in accordance with existing or new road authorizations issued to LADWP. Access road maintenance consists of those activities necessary to allow continued access to the ROW and/or each tower structure. These activities may include grading, and maintenance of drainage systems, bridges, culverts, fences, gates and signs. Motor graders, backhoes, dump trucks and pickups are used to maintain access roads.

1.11 DECOMMISSIONING OF TRANSMISSION LINES

At the end of the useful life of the proposed Project, if the facility were no longer required, or if extension of the authorizations were not granted by federal land agencies at the time they expired, the transmission line would be abandoned. Subsequently, conductors, insulators and hardware would be dismantled and removed from the ROW. Tower structures would be removed and foundations broken off below ground surface.

If the line and associated ROW are abandoned at some future date, the ROW would be available for the same uses that existed prior to construction of the Project. Following abandonment and removal of the transmission line from the ROW, any areas disturbed to dismantle the line would be restored and rehabilitated as near as possible to their original condition.

2.0 ADDITION OF NEW 230 KV CIRCUIT

Between the proposed Haskell Canyon Switching Station and the existing Castaic Power Plant, LADWP proposes the addition of 12 miles of a new 230 kV transmission circuit onto existing Castaic – Olive 230 kV Transmission Line structures (towers 1-1 through 12-1). This new circuit would be called Castaic – Haskell Canyon #4 and would utilize the same conductor (2,156 kcmil “Bluebird” ACSS/AW) as that proposed for the new 230 kV transmission line between Barren Ridge and Haskell Canyon Switching Stations.

The addition of a new circuit on existing towers would require many of the same activities of a new transmission line (surveying of ROW, rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, and cleanup). However, all work would be within existing ROW and no new towers would be constructed. Some towers may need to be modified or reinforced to carry the additional weight of the new conductor. Specific towers requiring reinforcement would be determined following detailed design of the Project. Tower reinforcement would not alter the general design or the location of the structures. This process would generally include reinforced foundations or steel member replacements.

3.0 RECONDUCTORING

LADWP proposes the reconductoring of 76 miles of the existing BR-RIN 230 kV transmission line with larger conductors between the Barren Ridge Switching Station and Rinaldi Substation (towers 176-1 through 251-1). The existing conductors (954/ 2,312 kcmil) would be replaced with a new 1,433.6 kcmil “Merrimack” ACSS/TW/HS conductor. The new conductor would have a larger diameter that allows for greater electrical capacity.

The upgrade of the existing BR-RIN would also require many of the same activities of the new transmission line (surveying of ROW, rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, and cleanup). Removal of the existing conductor would be used to string a pulling line, and this line would then be used to pull in the new conductor. All work would remain within the existing 250-foot-wide ROW, with no additional ROW required. Some of the towers would need to be

modified, replaced, and/or have foundations reinforced or replaced to carry the additional weight of the new heavier conductor.

4.0 NEW HASKELL CANYON SWITCHING STATION

As a component of the BRRTP, LADWP proposes the construction of a new switching station in Haskell Canyon, south of the Angeles National Forest on LADWP-owned property at the convergence of several existing and proposed 230 kV transmission lines (the existing BR-RIN, the proposed double-circuit Barren Ridge-Haskell Canyon, existing Castaic-Northridge, Castaic-Sylmar, Castaic-Olive, and the proposed Castaic to Haskell Canyon).

The station would be approximately 500 feet by 600 feet to accommodate the necessary circuit positions, which are made up of equipment, such as steel support structures, circuit breakers, disconnect switches, and associated equipment, and a relay house and control house containing control and protective relaying equipment. The relay and control houses would each be approximately 30 feet long by 12 feet wide by 10 feet high and constructed of gray concrete block. The station yard would include a paved internal access road approximately 16 feet wide and would be enclosed by chain-link fencing with barbed-wire extension for security. Figure 6 illustrates the preliminary design layout for the station. Figure 7 illustrates the preliminary grading plan for the station.

Necessary pre-construction geotechnical investigation on-site would include six borings by a drill rig to investigate bedrock and soil stability and four cone penetration test locations after site grading to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

Construction of the new Haskell Canyon Switching Station would consist of preconstruction surveys, clearing and grading of access roads, site grading and drainage development, installation of concrete foundations and steel support structures, installation of below- and above-ground electrical conduits for equipment power and control, installation of below- and above-grade grounding conductors, and installation of control and relay houses. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks, and flatbed trailers. Cranes, man-lifts, portable welding units, line trucks, and mechanic trucks would also be required. Construction would require an estimated 12 months with approximately 60 workers.

Site preparation work for the station would involve clearing and grading of access roads, clearing of the switchyard site, the cut and fill grading of the site, and placement and compaction of structural fill that would serve as a base for switching station facilities. The site would be graded to maintain current drainage patterns as much as possible. A 16-foot wide paved road and 100-foot by 100-foot gravel parking area would be required. The yard would be covered with crushed-rock aggregate. Native vegetation would be re-established where possible outside the switchyard fence.

Following site grading and development, reinforced concrete foundations would be installed to support the steel structures and electrical equipment and control facilities. It is estimated that 1,500 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 180 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 120-day working period. Subsequent to the foundation installation, trenches would be dug to facilitate placement of copper conductors for the station grounding mat.

Multiple transmission lines would be terminated into the switching station (i.e., the new and existing Barren Ridge – Haskell and Castaic – Haskell Canyon transmission lines) and would need support and

require the installation of galvanized steel structures. An existing 115 kV transmission line may need to be relocated around the proposed station. High-voltage bus work consisting of aluminum jumpers and tubing would be installed within the station.

PRELIMINARY IMPROVED ACCESS ROAD SUMMARY:

ROAD LENGTH	3,800 FT
ROAD WIDTH	
EXISTING	14 FT
PROPOSED	22 FT
MAXIMUM SLOPE	15 %
MINIMUM CENTERLINE RADIUS OF CURVES	80 FT

NOTES:

THE ALIGNMENT OF THE PROPOSED PAVED ACCESS ROAD FOLLOWS THAT OF THE EXISTING PATROL ROAD.

THE EXISTING ACCESS ROAD WILL NEED TO BE WIDENED AND PAVED TO ALLOW SERVICE VEHICLES ACCESS TO THE PROPOSED STATION. WIDENING THE ROAD WILL REQUIRE ADDITIONAL GRADING AND EARTHWORK.

THE PROPOSED ACCESS ROAD MAY BE SUBJECT TO THE APPROVAL THE LOS ANGELES COUNTY FIRE DEPARTMENT.

THE EARTHWORK QUANTITIES AND CONSTRUCTION COST ESTIMATES LISTED ON SHEET 1 DOES NOT INCLUDE THE CONSTRUCTION OF THE IMPROVED ACCESS ROAD.

IN THIS ALTERNATIVE, THE PROPOSED STATION EXTENDS INTO PRIVATE PROPERTY. RIGHTS TO THIS PRIVATE PROPERTY MUST BE ACQUIRED BY LADWP.

PLEASE NOTE THAT THIS DESIGN IS PRELIMINARY. THE TOPOGRAPHY, PROPRETY LINES, PROJECT LIMITS AND DESIGN VARIABLES ARE APPROXIMATE AND THUS SUBJECT TO CHANGE. A NUMBER OF REMAINING ENGINEERING AND ENVIRONMENTAL ISSUES MUST STILL BE RESOLVED. THIS EXHIBIT, AND CORRESPONDING CONSTRUCTION COST ESTIMATE, ARE FOR PRELIMINARY SITE EVALUATION PURPOSES ONLY.

5.0 EXPANSION OF BARREN RIDGE SWITCHING STATION

LADWP proposes expansion of the existing Barren Ridge Switching Station to the east side by 235 feet by 500 feet, for a total station size of 485 feet by 500 feet (approximately 5.6 acres). The expansion area of the station would include electrical structures and equipment for the addition of transmission lines, a material staging area, roadway within the station, and drainage area. Figure 8 illustrates the preliminary design layout for the station.

Expansion of the existing switching station would be very similar to the construction of the Haskell Canyon Switching Station as described above. Expansion would consist of preconstruction surveys, site preparation and grading, installation of reinforced concrete foundations, installation of electrical conduits for equipment power and control, and installation of structures and equipment.

Necessary pre-construction geotechnical on-site investigation would include two test pits excavated by a backhoe to investigate soil density and settlement, and four cone penetration test locations on-site to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

It is estimated that 700 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 80 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 90-day working period. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks and flatbed trailers. Cranes, man-lifts, portable welding units, line

trucks, and mechanic trucks would also be required. An estimated 8 months with approximately 60 workers would be required to expand the station.

APPENDIX A: PALEONTOLOGY IMPACT TABLES
APPENDIX B: DETAILED CONSTRUCTION, OPERATION, AND MAINTENANCE PROCESS

1.0 INTRODUCTION

The City of Los Angeles Department of Water and Power (LADWP) is proposing the Barren Ridge Renewable Transmission Project (BRRTP or Project) to access clean, renewable resources in the Tehachapi Mountains and Mojave Desert areas, and to improve reliability and upgrade transmission capacity.

LADWP, the US Department of Agriculture, Forest Service (USFS or Forest Service) and the U.S Department of the Interior, Bureau of Land Management (BLM) are preparing a joint Environmental Impact Statement (EIS) / Environmental Impact Report (EIR) for the proposed BRRTP. LADWP is the California Environmental Quality Act (CEQA) Lead Agency, while the USFS and BLM are the federal Co-Lead Agencies under the National Environmental Policy Act (NEPA). An EIS/EIR is an informational disclosure document used to inform agency decision makers and the public of the potential significant environmental effects of a project, identify possible ways to eliminate or minimize the potential significant effects, and describe reasonable alternatives to the Proposed Action /Project.

The purpose of the Paleontological Resources study is to provide an inventory of paleontological resources within the study area and to assess the potential impacts to these resources resulting from construction and operation of each of the proposed transmission line alternative corridors (Segments), addition of a new circuit onto existing structures, reconductoring of the existing transmission line, proposed switching station, and expansion of an existing switching station. The Paleontological Resources Assessment: 1) presents the regulatory framework, 2) provides an overview of the technical methodology used in collecting baseline conditions and evaluating impacts, 3) examines the affected environment within the study corridors and vicinity, 4) describes the potential impacts on paleontological resources from construction and operation of the Project, 5) evaluates the level of potential impacts based upon NEPA/CEQA criteria; and 6) presents specific recommendations for mitigation measures to reduce or eliminate potential impacts.

Paleontology is a multidisciplinary science that combines elements of geology, biology, chemistry and physics in an effort to understand the history of life on earth. Paleontological resources, or fossils, are the remains, imprints, or traces of once-living organisms preserved in sedimentary rocks. These include mineralized, partially mineralized, or unmineralized bones and teeth, soft tissues, shells, wood, leaf impressions, footprints, burrows, and microscopic remains. The fossil record is the only direct evidence that life on earth has existed for more than 3.6 billion years. Fossils are important scientific and educational resources because they are used to:

- Study the phylogenetic (i.e., evolutionary) relationships between extinct organisms, as well as their relationships to modern groups.
- Elucidate the taphonomic, behavioral, temporal, and diagenetic pathways responsible for fossil preservation, including the biases inherent in the fossil record.
- Reconstruct ancient environments, climate change, and paleoecological relationships.
- Provide a measure of relative geologic dating which forms the basis for biochronology and biostratigraphy, and which is an independent and corroborating line of evidence for radiometric dating.
- Study the past geographic distribution of organisms and tectonic movements of land masses and ocean basins through time.
- Study patterns and processes of evolution, extinction, and speciation.

Fossils are considered non-renewable resources because the organisms they represent no longer exist. Thus, once destroyed, a fossil can never be replaced. For the purposes of this report, paleontological resources can be thought of as including not only the actual fossil remains but also the collecting localities and the geologic rock units (i.e., formations) containing those localities.

1.1 STUDY PERSONNEL

This report was prepared by Thomas A. Deméré, Ph.D., a paleontologist with over 34 years of experience, Michael X. Kirby, Ph.D., a paleontologist with over 10 years of experience, and Sarah A. Siren, M.S. a paleontologist with over 7 years of experience. Dr. Deméré and Ms. Siren are current staff members of the Department of PaleoServices at the San Diego Natural History Museum (SDNHM), San Diego, California. Dr. Kirby is a former SDNHM staff member, but still consults for the Museum on an as-needed basis.

1.2 PROJECT DESCRIPTION

The BRRTP would be located in Kern and Los Angeles counties. As proposed by LADWP, it would be approximately 76 miles in length extending from the Barren Ridge Switching Station to Rinaldi Substation, and extending approximately 12 miles from the Castaic Power Plant to the proposed Haskell Canyon Switching Station. As shown in Figure 1-1, the proposed BRRTP would include the following:

1) Construction of approximately 61 miles of a new 230 kilovolt (kV) double-circuit transmission line from the LADWP Barren Ridge Switching Station to Haskell Canyon;
2) Addition of approximately 12 miles of a new 230 kV circuit on the existing double-circuit structures from Haskell Canyon to the Castaic Power Plant;
3) Reconductoring of approximately 76 miles of the existing Barren Ridge-Rinaldi (BR-RIN) 230 kV transmission line with larger capacity conductors between the Barren Ridge Switching Station and the Rinaldi Substation;
4) Construction of a new switching station in Haskell Canyon;
5) Expansion of the existing Barren Ridge Switching Station.

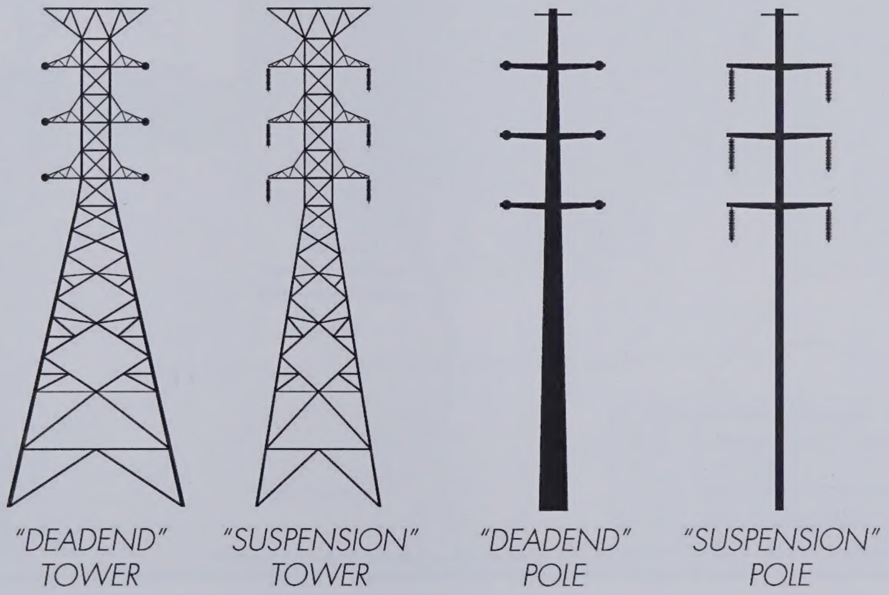
1.2.1 Construction of New 230 kV Double-Circuit Transmission Line

The proposed double-circuit 230 kV transmission line component of the BRRTP would consist of two alternating current (AC) circuits from the Barren Ridge Switching Station to the proposed Haskell Canyon Switching Station in Haskell Canyon.

The proposed structures for the new transmission line would primarily be self-supporting double-circuit steel lattice towers fabricated from galvanized steel members, as shown on the left side of Figure 1-2. Depending on the environmental conditions of the surrounding terrain, the height of the proposed lattice structures would range from 110 to 195 feet, with an average tower-to-tower span of 1,000 to 1,100 feet. Appendix B lists the structure specifications for the number of structures per mile, average span length, and average heights for towers and components. Exact structure placement would be determined during engineering surveys and detailed design studies for the selected Alternative route following the Record of Decision (ROD) on the EIS/EIR. A variety of engineering, constructability, existing access, and environmental issues would be considered during detailed structure siting within the permitted ROW.

"Dead-end" towers of self-supporting, steel-lattice design would be required periodically to add longitudinal strength along the line. Dead-end towers would also be used at turn (angle) locations along the line, at heavily loaded tower locations, and at specific utility crossings (e.g., other transmission lines) for added safety. Dead-ended towers are of the same basic configuration as suspension towers (non-angle structures), the difference being in the tower "arms," insulator systems, and tower weights.

FIGURE 1-2. TYPES OF TOWERS



Self-supporting, tubular steel poles (TSP) have been proposed by LADWP as an available mitigation structure where appropriate to reduce potential impacts, such as conflicts with cultivation on agricultural lands. The TSPs can reduce impacts in some cases due to a smaller footprint than the proposed self-supporting steel lattice structures; however, more TSPs per mile are necessary due to a shorter average span between structures. The TSPs would have an average height range between 95 and 180 feet, depending on the conditions of the surrounding terrain, with an average tower-to-tower span of 700 to 800 feet. Refer to Figure 1-2 for an illustration of the double-circuit poles.

For the majority of the alignment, the two new 230 kV circuits would be placed on new double-circuit transmission towers, but for approximately 1.5 miles, the circuits would be placed on existing four-circuit structures that are located just north of the proposed Haskell Canyon Switching Station. Between where the existing BR-RIN crosses Dry Canyon to the intersection of the Castaic transmission lines, LADWP has existing four-circuit towers with three vacant positions. The existing towers would be utilized in this section for the proposed 230 kV double circuit transmission line instead of constructing new towers. See Figure 1-3 for the location and illustration of the existing four-circuit towers to be utilized.

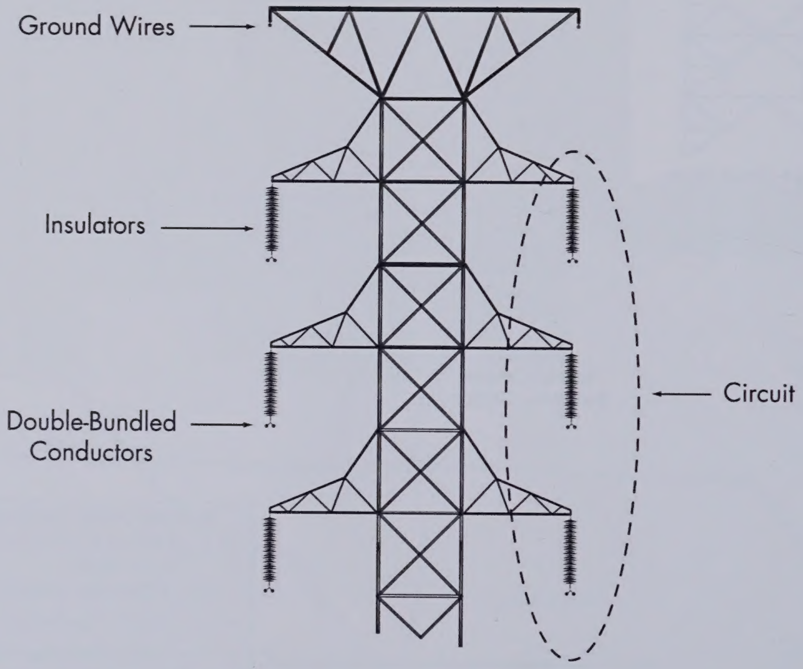
LA DWP

The self-supporting steel lattice structures and TSPs would utilize concrete foundations. Steel lattice structures would require four footings (one for each leg); TSPs would require single footings. Footings would be steel-reinforced concrete pier type and be cast in place. The typical design for the concrete footings for lattice structures would be between 2.5 and 5.0 feet in diameter, with an average depth of 20 feet depending on soil conditions. Typical design for single foundations for TSPs would include augured holes approximately five to seven feet in diameter and 15 to 30 feet deep, depending on conditions. Formwork steel reinforcing would be assembled in the hole prior to casting concrete in place. Reinforcing steel would become integral to the lower leg of the steel lattice structure during assembly. An above-ground concrete form placed over each hole would result in a final concrete foundation height of 0.5 to 2.0 feet above ground level.

As illustrated in Figure 1-4, Typical Tower Components, each tower carries conductors ("wires"), insulators, and ground wires. The conductor being considered for the new double-circuit 230 kV transmission line and installation of the Castaic – Haskell Canyon #4 circuit on existing structures is a bundled 715.5 kcmil "Starling" ACSS/AW. The reconductoring of the BR-RIN transmission line between Barren Ridge Switching Station and Rinaldi Substation would require a bundled 1,433.6 kcmil "Merrimack" ACSS/TW/HS conductor.

FIGURE 1-4. TYPICAL TOWER COMPONENTS



Each circuit would consist of three phases ("wires") as illustrated in Figure 1-4. To increase the current-carrying capability of the transmission lines and reduce power loss, the Proposed Action (Alternative 2) would utilize bundled conductors installed for each phase. The bundled conductors would consist of two conductor cables connected by a spacer. The new 230 kV double-circuit transmission line would consist of a total of six double-bundled (12 individual) wires.

Minimum conductor height above the ground, under normal operation of the line, is 30 feet. Greater clearances may be required in certain areas to allow for clearances over trees or other vegetation that

could pose a risk to the operation of the transmission line. Minimum conductor clearance would dictate the exact height of each tower based on topography and safety clearance requirements.

Insulators are used to provide the physical connection of conductors to structures. These system components are made of very low conducting materials (polymer insulators) that inhibit the flow of electric current from energized conductors to ground or to other energized system elements. Insulators and their associated hardware are to be configured in an "I" assembly to support conductors while maintaining required distances between phases and grounded structures. Each "I" string would consist of six-inch diameter insulators between six and eight feet long.

To shield conductors from hazard of direct lightning strikes by transferring lightning currents into the ground, overhead ground wires (shield wires) or fiber optic ground wire would be installed on top of new structures.

Construction of a transmission line involves the following general sequence of events: surveying activities; identifying and constructing access roads; clearing ROW and tower sites (including construction yards and batch plants); installing foundations; assembling and installing the towers; clearing, pulling, tensioning, and splicing; installing ground wires and conductors; installing counterpoise; switching station tie-in; and site upkeep and site reclamation. Various phases of construction would occur at different locations throughout the construction process for the BRRTP. This would require several contractors operating at the same time and in different locations. Refer to Appendix B for a description of each construction activity.

Existing paved and unpaved highways and roads would be used where possible. Roads along existing utility corridors would also be used where possible to minimize new access road construction. In locations where existing roads could be used, that are located in close proximity to the proposed or existing ROW centerlines, only new spur roads to the tower sites would be constructed. The specific locations and design of all new access and spur roads would be determined during final Project design.

It is anticipated that one or two construction yards or staging areas would be required for materials storage, construction equipment, construction vehicles, and temporary construction offices. Staging areas would be approximately five acres in size, and located centrally or near each end of the transmission line route. The staging areas would likely be located on previously disturbed land and would be level and surfaced with crushed aggregate base. The LADWP would negotiate with landowners for specific locations of the staging areas.

Routing

In 2007, a siting analysis was conducted to identify appropriate sites for a new 230 kV transmission line. Over 200 miles of routing opportunities were identified and referred to as Segments A through I (see Figure 1-5). These segments were then combined to create end-to-end routing "alternatives" as discussed in Section8.2. All routing Segments were identified assuming the need for a 200-foot ROW for the new 230 kV transmission line and the use of conventional transmission line construction. However, as discussed in Section 8.2, the end-to-end alternatives have included specific mitigation measures to reduce certain impacts. These mitigation measures would eliminate the need for new ROW in some locations and would require the use of helicopters for tower assembly in designated areas on the ANF. Also, to the maximum extent possible, all existing access and spur roads would be utilized for the construction, operation, and maintenance of the BRRTP. Below is a brief description of each segment.

Segment A is 13 miles long and runs from LADWP's Barren Ridge Switching Station to the unincorporated community of Mojave, California. It would traverse four miles of BLM managed public lands and parallel LADWP's existing 230 kV Barren Ridge – Rinaldi Transmission Line (BR-RIN) and the 500 kV Pacific Direct Current Intertie (PDCI). It traverses four miles of BLM-managed lands.

Segment B is 27 miles long and starts just north of the unincorporated community of Mojave, California and travels south to a point one mile east of the Antelope Valley California Poppy Reserve. This segment parallels LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines for its entire length.

Segment C is 22 miles long and begins at the location as Segment B, north of the unincorporated community of Mojave, California. Segment C parallels the Los Angeles Aqueduct in a southwest direction to Cottonwood Creek. No existing transmission lines are located within the aqueduct corridor; however, Southern California Edison's (SCE's) Tehachapi Renewable Transmission Project's (TRTP) Alternative 10A is also proposed along the same corridor.

Segment D is 48 miles long and would traverse 16 miles of National Forest System (NFS) lands. This segment generally parallels the Los Angeles Aqueduct in a southwest direction, beginning near Cottonwood Creek and traveling to Lancaster Road. It then travels west to the Interstate 5 freeway utility corridor and continues southeast along LADWP's existing Castaic – Rinaldi corridor to the proposed Haskell Canyon Switching Station. Five high voltage transmission lines are located along the Interstate 5 section of the segment. Oil and gas pipelines are also located in the same I-5 corridor. Continuing further south near Castaic Power Plant, Segment D would be located to the south of two existing LADWP double-circuit 230 kV transmission line towers until reaching the proposed Haskell Canyon Switching Station.

Segment E is 11 miles long and begins near Cottonwood Creek at the intersection of Segments C and D. Segment E travels in a southeast direction and intersects Segment B one mile east of the Antelope Valley California Poppy Reserve. Three existing high voltage transmission lines (Midway-Vincent 500 kV, Antelope-Vincent 230 kV, and Antelope-Mesa 230 kV) are located within the corridor that Segment E would parallel. SCE's proposed TRTP Segment 4 is also proposed adjacent this same corridor.

Segment F is the shortest segment, at four miles in length, and begins at the intersection of Segments B and E one mile east of the Antelope Valley California Poppy Reserve. Three existing high voltage transmission lines (Midway-Vincent 500 kV, Antelope-Vincent 230 kV, and Antelope-Mesa 230 kV) are also located parallel to this segment.

The 115th Street Segment was proposed as a modification to avoid impacts to residents in the Antelope Valley near Segments F and H, described below. It begins mid-way within Segment F near SCE's Antelope Substation and parallels 115th Street south to the California Aqueduct. No existing transmission lines occur within this corridor; however, TRTP's proposed Segment 4 would be located along this alignment. This segment would split Segments F and H as shown in Figure 1-5 creating these Segments into F1, F2, H1 and H2.

Segment G is 21 miles long. Thirteen miles traverse National Forest System (NFS) lands. It travels south from the intersection of Segments B and F one mile east of the Antelope Valley California Poppy Reserve to the proposed Haskell Canyon Switching Station, located near the southern boundary of the ANF. It is a designated utility corridor containing LADWP's existing 230 kV BR-RIN and 500 kV PDCI lines. The BRRTP proposes to use its existing four-circuit structures for two miles, from towers 234-3 to 236-2 (see Figure 1-3).

Segment 2a is seven miles long. It would bypass the unincorporated community of Green Valley and follow an existing fire road through ANF. Segment 2a would not parallel existing transmission facilities, and a new utility corridor would be required.

Segment H is 20 miles long and would parallel SCE's Antelope-Pardee line. It starts near SCE's Antelope Substation at the intersection of Segments F and I and traverses 13 miles of NFS lands to the proposed Haskell Canyon Switching Station. As requested by the USFS, all portions of this segment that fall within the northern and southern borders of the ANF would be constructed entirely by the use of helicopters. The helicopter construction requirement was established by the USFS for consistency of transmission line construction within the existing Antelope-Pardee transmission line corridor. No new access roads would be constructed except those required for pulling and tensioning sites or staging locations for construction materials. The addition of the 115th Street Segment, described above, splits the Segment into H1 (northern portion) and H2 (southern portion).

Segment I is 32 miles long. It begins near the Antelope Substation at the intersection of Segments F and H, and heads southeast through the City of Palmdale, parallel SCE's existing high voltage transmission lines (Midway-Vincent 500 kV, Antelope-Vincent 230 kV, and Antelope-Mesa 230 kV). The segment continues directly south to an existing LADWP transmission line corridor, then continues in a southeast direction to the proposed Haskell Canyon Switching Station, parallel LADWP's existing high voltage transmission lines (Victorville-Rinaldi 500 kV and Adelanto-Rinaldi 230 kV). A majority of this segment would be located outside of NFS lands. Two miles would be located on NFS lands.

Segment J is located parallel to the southern portion of Segment D. Segment J would consist of a new single 230 kV circuit to be placed on existing double-circuit towers between Castaic Power Plant and the proposed Haskell Canyon Switching Station (see discussion in Section 1.2.2 below).

Three-Circuit Tower Mitigation

In areas where there are ROW expansion constraints and where LADWP has existing 230 kV transmission lines, LADWP is proposing to construct three-circuit towers within the existing ROW to carry the existing BR-RIN circuit and the two proposed Barren Ridge to Haskell Canyon (BR-HC) circuits. This would avoid various impacts, including the acquisition of residential property in the unincorporated communities of Willow Springs (milepost 27.1 to 27.6) and Elizabeth Lake and Green Valley (milepost 44.6 to 51.7). Refer to Figure 1-6 for an illustration of three-circuit tower types, and to Figure 1-7, the Three-Circuit Tower Mitigation Map, for proposed locations.

L.A. DWP

LADWP must maintain the electrical service along the existing BR-RIN transmission line to avoid impacts to the hydroelectric power plants north of the Barren Ridge Switching Station. Therefore, a temporary transmission line would be constructed to keep the BR-RIN circuit energized during construction of the three-circuit towers. After the temporary line is constructed, the existing BR-RIN single-circuit towers would be removed to allow the new three-circuit towers to be constructed within the existing ROW. Once construction of the three-circuit towers is completed, the temporary transmission line would be removed. The temporary transmission line is expected to be in place from six to nine months.

The temporary transmission line would be 7.5 miles long and would consist of wood and steel single poles with an average height of 95 feet, a 3-foot by 3-foot footprint, and an average of eight poles per mile. Construction would occur within a new temporary 80- to 100-foot ROW. The majority of the temporary transmission line would be constructed along San Francisquito Road. Portions would also be constructed along Elizabeth Lake Road and Johnson Road. Pole placement would be adjacent to public roadways wherever possible. If necessary, temporary ROW on private property would be needed where poles could not be placed within public road ROW. The majority of poles would be direct-embedded when set in place and would not require a permanent foundation. Where additional strength is necessary at larger angle points, steel poles would be required, which could require an excavation approximately 6 feet in diameter by 20 feet deep to accommodate the concrete pier foundation that would be cast in place. Once all the poles have been constructed and the conductor installed, the existing BR-RIN circuit would be connected into the temporary line and energized. The construction would require establishment of a staging area, work areas around poles, and pull and tension sites. Access to pole sites and pull and tension sites would be from the adjacent roadways.

Approximately seven miles of the existing BR-RIN single-circuit towers would be removed, with existing ROW utilized to access the existing towers. The new three-circuit towers would be placed within the existing ROW, utilizing existing access roads. Helicopter Mitigation, as described in this section below, would be applied in steeper terrain if additional access is required. The new three-circuit tower would require a 25-foot by 30-foot structure footprint and an average of seven structures per mile; the average structure height would be 170 feet, with a maximum tower-to-tower span length of 780 feet. The construction process for the new three-circuit towers would be the same as the double-circuit towers discussed above. After completion of construction of the three-circuit towers, the temporary transmission line would be removed and all temporary staging and work area land disturbances would be restored as close to previous conditions as possible and revegetated as required.

Helicopter Mitigation

Within the ANF where the terrain is steep and access is limited, the USFS would require that the new double-circuit 230 kV structures be constructed with the use of helicopters (such as the Hughes 500 or Bell 212, or Sikorsky Skycrane). Although no specific locations for this mitigation have been identified for the Proposed Action, as defined, it is expected USFS would require the helicopter mitigation for construction in any area more than 300 feet from an existing road and with slopes greater than approximately 25 percent. The use of helicopters for the construction of transmission tower structures would eliminate the need for new access roads to structure locations, and would therefore minimize land disturbance associated with crane pads, structure laydown areas, and the trucks and tractors used for delivery of structures to sites. However, the following site and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas and associated access roads, tower structure vegetation clearing, guard structures at major crossings, and access road pullouts.

Temporary 24-foot wide access roads would be required to access the helicopter fly yards/staging areas. The transmission line materials (tower steel, conductor reels, structure hardware, etc.) would be delivered by truck to the helicopter fly yards/staging areas. Vegetation clearing may be required at these sites to

ensure safe working conditions. The fly yards/staging areas would serve as helicopter support yards for fueling and maintenance, as well as for the transport of materials and personnel. Towers may also be assembled in sections at these yards prior to delivery to the tower sites. Heavy lift helicopters would then fly the towers from the yards to the tower sites.

Portable landing pads would be located at each tower site. These pads would allow helicopters to load and unload personnel, tools, and equipment necessary for construction of foundations and assembly of tower structures. Helicopter-constructed towers that would not be in close proximity to existing access roads would utilize micropile foundations. For each tower leg, micropile foundations would use a group of three to eight 6- to 9-inch diameter casings that would be drilled and grouted into the ground. The exposed portion of the pile group would be encased in a reinforced concrete cap from the top of the casings to a depth anywhere from one to eight feet below the ground surface, depending on the terrain.

Conductor installation would proceed in the same manner as the double-circuit tower installation. The equipment necessary for conductor installation would be large, heavy construction equipment that could only be brought in by truck. Some NFS roads could need maintenance or improvement to allow pulling and tensioning, but no new access or spur roads would be created for conductor installation on the helicopter-constructed towers. After project completion, any maintained access roads to helicopter fly yards/staging areas to would be reduced to 16 feet.

1.2.2 Addition of New 230 kV Circuit

Between the proposed Haskell Canyon Switching Station and the existing Castaic Power Plant, LADWP proposes the addition of 12 miles of a new 230 kV transmission circuit onto existing Castaic – Olive 230 kV Transmission Line structures. The circuit would cross the unincorporated communities of Castaic and Saugus and the city of Santa Clarita. A total of 300 feet of BLM-managed public lands and four miles of NFS lands would be traversed; however, the new circuit would not require a new or additional ROW. This new circuit would be called Castaic – Haskell Canyon #4 and would utilize the same conductor (bundled 715.5 kcmil "Starling" ACSS/AW [aluminum conductor steel supported/aluminum-clad steel wire]) as that proposed for the new 230 kV transmission line between Barren Ridge and Haskell Canyon Switching Stations.

The addition of a new circuit on existing towers would require many of the same construction activities associated with a new transmission line (refer to Appendix B for a description of each construction activity). However, all work would be within existing ROW and no new towers would be constructed. Some towers may need to be modified or reinforced to carry the additional weight of the new conductor. Specific towers requiring reinforcement would be determined following detailed design of the Project. Tower reinforcement would not alter the general design or the location of the structures. This process would generally include reinforced foundations or steel member replacements. Refer to Figure 1-1 for a map showing the location of the new 230 kV circuit.

1.2.3 Reconductoring of Existing Transmission Line

LADWP proposes the reconductoring of 76 miles of the existing BR-RIN 230 kV transmission line with larger conductors from the Barren Ridge Switching Station to Rinaldi Substation. Four miles of BLM-managed public lands, 13 miles of National Forest System (NFS) lands, and 44 miles of private property would be traversed. The existing conductors (954/ 2,312 kcmil) would be replaced with a new 1,433.6 kcmil "Merrimack" ACSS/TW/HS (aluminum conductor steel supported/trapezoidal wires/high strength) conductor. The new conductor would have a larger diameter that allows for greater electrical capacity.

The upgrade of the existing BR-RIN would also require many of the same activities of the new transmission line (surveying of right-of-way [ROW], rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, and cleanup). Removal of the existing conductor would be used to string a pulling line, and this line would then be used to pull in the new conductor. All work would

remain within the existing 250-foot-wide ROW, with no additional ROW required. Some of the towers would need to be modified, replaced, and/or have foundations reinforced or replaced to carry the additional weight of the new heavier conductor. Refer to Figure 1-1 for the location of the reconductoring.

1.2.4 Construction of New Switching Station

As a component of the BRRTP, LADWP proposes the construction of a new switching station in Haskell Canyon, south of the Angeles National Forest on LADWP-owned property at the convergence of several existing and proposed 230 kV transmission lines (the existing BR-RIN, the proposed double-circuit Barren Ridge – Haskell Canyon, existing Castaic – Northridge, Castaic – Sylmar, Castaic – Olive, and the proposed Castaic – Haskell Canyon). Refer to Figure 1-1 for the location of the new switching station.

The station would be approximately 500 feet by 600 feet to accommodate the necessary circuit positions, which are made up of equipment, such as steel support structures, circuit breakers, disconnect switches, and associated equipment, and a relay house and control house containing control and protective relaying equipment. The relay and control houses would each be approximately 30 feet long by 12 feet wide by 10 feet high and constructed of gray concrete block. The station yard would include a paved internal access road approximately 16 feet wide and would be enclosed by chain-link fencing with barbed-wire extension for security. The preliminary grading plan for the station is located in Appendix B.

Necessary pre-construction geotechnical investigation on-site would include six borings by a drill rig to investigate bedrock and soil stability and four cone penetration test locations after site grading to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

Construction of the new Haskell Canyon Switching Station would consist of preconstruction surveys, clearing and grading of access roads, site grading and drainage development, installation of concrete foundations and steel support structures, installation of below- and above-ground electrical conduits for equipment power and control, installation of below- and above-grade grounding conductors, and installation of control and relay houses. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks, and flatbed trailers. Cranes, man-lifts, portable welding units, line trucks, and mechanic trucks would also be required. Construction would require an estimated 12 months with approximately 60 workers.

Site preparation work for the station would involve clearing and grading of access roads, clearing of the switchyard site, the cut and fill grading of the site, and placement and compaction of structural fill that would serve as a base for switching station facilities. The site would be graded to maintain current drainage patterns as much as possible. A 16-foot-wide paved road and a 100-foot by 100-foot gravel parking area would be required. The yard would be covered with crushed-rock aggregate. Native vegetation would be re-established where possible outside the switchyard fence.

Following site grading and development, reinforced concrete foundations would be installed to support the steel structures and electrical equipment and control facilities. It is estimated that 1,500 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 180 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 120-day working period. Subsequent to the foundation installation, trenches would be dug to facilitate placement of copper conductors for the station grounding mat.

Multiple transmission lines would be terminated into the switching station (i.e., the new and existing Barren Ridge – Haskell and Castaic – Haskell Canyon transmission lines) and would need support and require the installation of galvanized steel structures. An existing 115 kV transmission line may need to

be relocated around the proposed station. High-voltage bus work consisting of aluminum jumpers and tubing would be installed within the station.

1.2.5 Expansion of Existing Switching Station

LADWP proposes expansion of the existing Barren Ridge Switching Station to the east side by 235 feet by 500 feet, for a total station size of 485 feet by 500 feet (approximately 5.6 acres). The expansion area of the station would include electrical structures and equipment for the addition of transmission lines, a material staging area, roadway within the station, and a drainage area. The preliminary design layout for the station may be found in Appendix B. Refer to Figure 1-1 for the location of the existing switching station.

Expansion of the existing switching station would be very similar to the construction of the Haskell Canyon Switching Station as described above. Expansion would consist of preconstruction surveys, site preparation and grading, installation of reinforced concrete foundations, installation of electrical conduits for equipment power and control, and installation of structures and equipment.

Necessary pre-construction geotechnical on-site investigation would include two test pits excavated by a backhoe to investigate soil density and settlement, and four cone penetration test locations on-site to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

It is estimated that 700 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 80 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 90-day working period. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks, and flatbed trailers. Cranes, man-lifts, portable-welding units, line trucks, and mechanic trucks would also be required. An estimated eight months with approximately 60 workers would be required to expand the station.

1.2.6 Project-Wide Mitigation Measures

To address potential impacts of the Proposed Project to multiple resource areas as discussed above, the following project-wide mitigation measure would be applied:

> Three-Circuit Tower Mitigation (THREE-CIRCUIT) – A three-circuit lattice tower design would be implemented as described in Section 1.2.1 of this Technical Report, at the locations shown in Figure 1-7, Three-Circuit Tower Mitigation Map.
>
> Helicopter Mitigation (HELICOPTER) – Helicopter Mitigation shall be implemented, as described in Section 1.2.1 of this Technical Report, in steep areas of the Angeles National Forest where access is limited. For Alternatives 1 and 2a, implementation would occur at the locations shown on Figure 8-2, Identified Helicopter Mitigation Map. During final design of the Project, areas other than those shown on Figure 8-2, including Alternatives 2 and 3, may potentially require helicopter construction of the towers. This determination would generally be made where tower sites have no existing access roads within 300 feet and slopes are greater than 25 percent. Final identification of these tower sites would be determined and agreed upon by USFS, BLM and LADWP.

1.2.7 Construction Work Force and Schedule

The NEPA Record of Decision and CEQA Notice of Determination (anticipated in the early part of 2012) must be made before construction could begin. Therefore, construction of the BRRTP is anticipated to

begin no sooner than summer 2012, with a target in-service date of early 2015. These dates are subject to change based on actual completion of design.

The following construction estimates were based on preliminary engineering and the number of workers and construction duration values are estimates; therefore, they are subject to change based on final engineering and design. The new double-circuit 230 kV transmission line from the Barren Ridge Switching Station to the proposed Haskell Canyon Switching Station would require 12.5 months and 134 workers. The installation of a 230 kV circuit on existing double-circuit towers from the Castaic Power Plant to the proposed Haskell Canyon Switching Station would require a month and a half and 35 workers. The upgrade and reconductoring of the existing BR-RIN would require eight months and 155 workers. The construction of a new 400-foot by 600-foot Haskell Canyon Switching Station would require 12 months and 60 workers. The expansion of the existing Barren Ridge Switching Station would require eight months and 60 workers.

The BRRTP components are anticipated to be constructed in the staggered sequence illustrated below in Tables 1-1 and 1-2. The construction of all Project components would take approximately two years and 447 total workers, with 173 workers at the peak of construction. Table 1-2 summarizes the BRRTP's anticipated construction workforce and schedule based on the most current information available. To allow for any delays in the Project, three weeks of float time were included for the new 230 kV transmission line and reconductoring efforts, and an additional two weeks of float time were included for the stringing of the second circuit between Castaic Power Plant and Haskell Canyon.

TABLE 1-1. ANTICIPATED CONSTRUCTION SEQUENCE

PROJECT COMPONENT	ANTICIPATED CONSTRUCTION SEQUENCE
Expansion of Barren Ridge Switching Station	Weeks 8 – 73
New Haskell Canyon Switching Station	Weeks 1 – 67
New 230 kV Transmission Line	Weeks 42 – 113
Reconductor BR-RIN	Weeks 55 – 88
Addition of 230 kV Circuit	Weeks 51 – 56

TABLE 1-2. CONSTRUCTION WORKFORCE AND SCHEDULE

PROJECT COMPONENT	CONSTRUCTION (START AND END WEEKS)	CONSTRUCTION DURATION (MONTHS)	TOTAL # OF WORKERS	PEAK # OF WORKERS AT ANY GIVEN TIME
Expansion of Barren Ridge Switching Station	8 – 73	15	60	38
New Haskell Canyon Switching Station	1 – 67	15.4	63	38
New 230 kV Transmission Line	42 – 113	16.5	134	131
Reconductor BR-RIN	55 -88	9	155	120
Addition of 230 kV Circuit	51 – 56	1.5	35	35
ALL COMPONENTS	**Weeks 1 – 113**	**26.1 months**	**447 Total Workers**	**173* Peak Workers**

*The value represents the total for the staggered construction of the Project components; it is not reflective of the sum of all the components.

2.0 REGULATORY FRAMEWORK

Fossils are classified as non-renewable scientific resources and are protected by various laws, ordinances, regulations and standards (LORS) across the country. Professional standards for the assessment and mitigation of adverse impacts to paleontological resources have been established by the Society of Vertebrate Paleontology (SVP) (1995). Pertinent LORS are summarized and discussed below. This paleontological study was conducted in accordance with the LORS which are applicable to paleontological resources within the study area and the professional standards and guidelines established by the SVP.

2.1 FEDERAL

The American Antiquities Act of 1906 1(6 USC 431-433). Establishes a penalty for disturbing or excavating any historic or prehistoric ruin or monument or object of antiquity on federal lands has a maximum fine of $500 or 90 days in jail.

The National Environmental Policy Act of 1969, as amended (Pub. L. 91-190, 42 U.S.C. 4321-4347, January 1, 1970, as amended by Pub. L. 94-52, July 3, 1975, Pub. L. 94-83, August 9, 1975, and Pub. L. 97-258 § 4(b), Sept. 13, 1982). Recognizes the continuing responsibility of the Federal Government to "preserve important historic, cultural, and natural aspects of our national heritage . . ." (Sec. 101 [42 USC § 4321]) (#382).

The National Historic Preservation Act (Pub. L. 89-665; 80 Stat. 915, 16 U.S.C. 470 et seq.). Provides for the survey, recovery, and preservation of significant paleontological data when such data may be destroyed or lost due to a federal, federally licensed, or federally funded project.

The Federal Land Management and Policy Act of 1976 (43 U.S.C. 1712[c], 1732[b]); sec. 2, Federal Land Management and Policy Act of 1962 [30 U.S.C. 611]; Subpart 3631.0 et seq.), Federal Register Vol. 47, No. 159, 1982. Defines significant fossils as: unique, rare or particularly well-preserved; an unusual assemblage of common fossils; being of high scientific interest; or providing important new data concerning [1] evolutionary trends, [2] development of biological communities, [3] interaction between or among organisms, [4] unusual or spectacular circumstances in the history of life, [5] or anatomical structure.

The Paleontological Resources Preservation Act of March 2009: P.L. 111-011. First statute to preserve paleontological resources on USFS, BLM, and U.S Department of the Interior, Bureau of Reclamation (BOR) lands. This law essentially codifies collecting polices of federal land management agencies. It allows reasonable amounts of common invertebrate and plant fossils to be casually collected with negligible disturbance. In addition, it requires protection and preservation of uncommon invertebrate and plants and all vertebrate fossils, including imprints, molds, casts, etc.

Federal protection for scientifically significant paleontological resources applies to projects if any construction or other related project impacts occur on federally owned or managed lands, involve the crossing of state lines, or are federally funded.

2.2 STATE

The Guidelines for the Implementation of CEQA, as amended March 29, 1999 (Title 14, Chapter 3, California Code of Regulations: 15000 et seq.). Defines procedures, types of activities, persons, and public agencies required to comply with CEQA, and include as one of the questions to be answered in the Environmental Checklist (Section 15023, Appendix G, Section XIV, Part a) the following: "Will the proposed project directly or indirectly destroy a unique paleontological resource or site or unique geologic feature?"

Other state requirements for paleontological resource management are included in the Public Resources Code (Chapter 1.7), Section 5097.5 and 30244. These statutes prohibit the removal of any paleontological site or feature on public lands without permission of the jurisdictional agency, defines the removal of paleontological sites or features as a misdemeanor, and requires reasonable mitigation of adverse impacts to paleontological resources from developments on public (state) lands.

3.0 PROJECT AREA OVERVIEW

3.1 NATURAL ENVIRONMENT IN THE STUDY AREA

The Project study area lies in a region of complex geology that straddles a major tectonic plate boundary between the North American lithospheric plate on the northeast and the Pacific lithospheric plate on the southwest. The modern plate boundary is formed by the San Andreas Fault Zone—a zone of deformation characterized by right-lateral strike-slip faulting of continental proportions. Geologic rock units of the southwestern block have been uplifted, forming the central portion of the Transverse Ranges, while the generally undeformed rock units of the northeastern block occupy an area of relatively low relief that forms the Antelope Valley portion of the Mojave Desert. Geologically, the Mojave Desert Province is characterized by broad alluvial basins that are being filled by sediments derived from the adjacent uplands (Tehachapi Mountains and Transverse Ranges). In Antelope Valley these alluvial deposits reach a thickness of 4,000 feet and have buried an older landscape eroded into Paleozoic metamorphic and sedimentary rocks and Mesozoic plutonic igneous rocks. Cenozoic sedimentary rocks also occur in this province, but have limited surface exposure primarily adjacent to the Garlock and San Andreas fault zones. Geologically, the Transverse Ranges Province is characterized by a series of generally east-west oriented mountain ranges separated by broad alluvial-filled valleys, narrow stream canyons, and major and minor faults. Rocks exposed in this portion of the Project study area are extremely diverse in origin and composition and include Precambrian and Paleozoic metamorphic and plutonic igneous rocks; Mesozoic metamorphic, plutonic, and sedimentary rocks; and Cenozoic marine and non-marine sedimentary rocks. The Mesozoic and Cenozoic sedimentary rocks contain a rich paleontological record that preserves portions of the last 75 million years of Earth history. Certain time intervals are especially well represented including the Cretaceous-Tertiary boundary (~65 Ma), the middle and late Miocene (~17 to 5 Ma), and the Pliocene and early Pleistocene (~4 to 1 Ma).

The following is a discussion of the general geology, paleontology, and distribution of the geologic rock units (formations) underlying the Project study area (Figure 3.1). A detailed inventory of geologic rock units for every tenth of a mile along the various proposed Project alternatives is provided in Appendix A.

3.1.1 Quaternary Alluvium

General Geology: Modern drainages contain unconsolidated stream and alluvial sediments of relatively recent age deposited by the permanent or ephemeral streams that flow in them. These sediments consist primarily of gravel, sand, and silt associated with the Santa Clara River and its tributaries (Oakeshott, 1958), as well as localized drainages and alluvial fans along the southern and northeastern borders of Antelope Valley (Dibblee, 1967). These deposits are assumed to be Holocene in age (0 to 10,000 years old). Quaternary alluvium is underlain by marine to terrestrial deposits of Tertiary to Cretaceous age in the Transverse Ranges Province (Oakeshott, 1958) and by terrestrial deposits of Quaternary and Tertiary age in the Mojave Desert Province (Dibblee, 1967).

Paleontology: Any organic remains (e.g., sub-fossils) preserved within the Quaternary alluvium are too young to be considered paleontological resources, because of the recent age of these deposits and their close association with modern drainages.[1]

Distribution: Quaternary alluvium occurs over large portions of the study area including all of segments A (MP 0.0 to 13.2), B (MP 0.0 to 26.5), C (MP 0.0 to 21.7), F1 (MP 0.0 to 0.8), and F2 (MP 0.0 to 2.8), the northern portions of segments D (MP 0.0 to 16.7), E (MP 0.0 to 6.8), G (MP 0.0 to 3.7), H1 (MP 0.0 to 1.8), and I (MP 0.0 to 4.5), and minor portions of Segment H2 (MP 0.8 to 1.1 and MP 1.5 to 1.9).

3.1.2 Older Alluvium

General Geology: Older alluvium consisting of poorly consolidated mudstones, sandstones, and cobble to boulder conglomerates deposited in ancient stream-channels and alluvial fans locally occur in the Study Area. In the Transverse Ranges the older alluvial deposits are primarily preserved as isolated, uplifted and eroded remnant terraces (Oakeshott, 1958), while in the Mojave Desert these deposits typically occur as locally faulted sequences of ancient alluvial fans (Dibblee, 1967). Older alluvial deposits vary in stratigraphic thickness from a few feet to as much as 200 feet (Oakeshott, 1958). During the windshield survey older alluvial deposits as observed in Green Valley consisted of poorly consolidated pebbly and gravelly sandstones overlying deeply weathered plutonic igneous rocks. Farther south along San Francisquito Creek localized older alluvium occurs in localized channels eroded into sedimentary rocks of the San Francisquito Formation. The geologic age of the older alluvium is not well constrained, but most likely ranges from early to late Pleistocene in age (Oakeshott, 1958).

Paleontology: Although no fossils are presently known from the older alluvium in the study area, similar deposits have produced significant remains of Pleistocene megafauna (e.g., ground sloth, mammoth, and mastodon) from sites elsewhere in Southern California (Jefferson, 1991).

Distribution: Deposits mapped as older alluvium have been mapped by Dibblee (1967) as erosional remnants of Pleistocene stream courses and alluvial fans in several portions of the study area including Segment E (MP 6.8 to 9.0), Segment G (MP 3.7 to 4.1, MP 7.8 to 8.9, MP 10.6 to 11.0, MP 16.1 to 17.6), Segment H1 (MP 1.8 to 2.3), and Segment I (MP 4.5 to 4.7, MP 8.3 to 8.8, portions of the segment between MP 14.8 and 16.0, MP 18.9 to 19.3, and MP 28.6 to 28.7).

3.1.3 Saugus Formation

General Geology: The Saugus Formation consists of 650 feet of poorly consolidated, coarse-grained sandstone and conglomerate that formed in fluvial and alluvial-fan paleoenvironments around the western end of the San Gabriel Mountains (Kew, 1924; Oakeshott, 1950, 1958). Hershey (1902) originally proposed the name "Saugus Division" for a series of alluvial deposits in Soledad Canyon near Saugus. Oakeshott (1958) later restricted the name "Saugus formation" to lower Pleistocene continental beds unconformably above the upper Pliocene Sunshine Ranch Member of the Pico Formation and lying with an angular unconformity below upper Pleistocene terrace deposits. Squires et al. (2006) continued this usage, although previous workers have placed marine deposits of the Pico Formation into the lower Saugus Formation (e.g., White, 1983; Groves, 1991a) (see White [1983] and Squires et al. [2006] for a discussion of the history of the stratigraphic nomenclature of the Pico and Saugus formations). As observed during the windshield survey, the Saugus Formation in the study area consists of flat-lying to gently dipping, non-marine strata including light red-brown, interbedded coarse-grained sandstones and pebble to cobble conglomerates. The age of the Saugus Formation is late Pliocene to early Pleistocene (~3 to 1.5 Ma). The Saugus Formation unconformably overlies different rock units depending on local geological conditions. In the Haskell Canyon area (segments G and J) the Saugus Formation overlies steeply dipping strata of the Castaic and Mint Canyon formations of Miocene age (Dibblee, 1996). Locally, the Saugus Formation is unconformably overlain by older alluvial deposits of late Pleistocene age (Oakeshott, 1958).

Paleontology: The Saugus Formation contains very fossiliferous marine deposits, as well as terrestrial deposits that locally contain fossil vertebrates. Marine fossils from the Saugus Formation include bryozoans, brachiopods, crabs, barnacles, gastropods, bivalves, echinoids, fish, and trace fossils (Eldridge and Arnold, 1907; Kew, 1924; Grant and Gale, 1931; Winterer and Durham, 1962; Squires and White, 1983; Groves, 1991a; Govean, 1993). Fossil bony fish include sheepshead (*Semicossyphus pulcher*), barracuda (*Sphyraena* sp.), and banjo fish (*Rhinobatos* sp.) (Govean, 1993). Terrestrial vertebrate fossils include terrapins, tortoises, and lizards, as well as land mammals, such as extinct rabbit, gopher, pack rat, dog, cat, mastodon, tapir, horse, peccary, camel, deer, and bison in the areas of the city of Santa Clarita and the San Fernando Valley (Winterer and Durham, 1954, 1962). Fossil land mammals have also been found elsewhere in the Saugus Formation; most notably extinct rabbit, gopher, pack rat, mammoths, horse, and llama of Irvingtonian-land-mammal age in Moorpark, California (Wagner et al., 2007).

Distribution: The Saugus Formation within the study area occurs along Segment D (MP 46.6 to 46.7, 47.3 to 47.4, and 47.5 to 47.6), Segment G (MP 19.1 to 20.9), Segment J (portions of the segment between MP 0.4 and 3.1), and Segment K (portions of the segment between MP 1.6 and 14.3).

3.1.4 Anaverde Formation

General Geology: The Anaverde Formation as exposed along the San Andreas Fault Zone in Leona Valley and Anaverde Valley consists of about 1,500 feet of terrestrial and fluvial sedimentary rocks (Wallace, 1949; Dibblee, 1967). Wallace (1949) formally named and mapped the Anaverde Formation after the Anaverde Valley and subdivided it into three distinct facies including a gray-white arkosic sandstone and cobble conglomerate facies, a gray, clay shale facies, and a diorite-clast breccia facies. The formation is locally deformed by faulting and overlies and is in fault contact with pre-Tertiary rocks (Dibblee, 1967). The Anaverde Formation is believed to be of late Miocene to early Pliocene age (~ 6 to 5 Ma) (Savage et al., 1954).

Paleontology: Fossils are rare in the Anaverde Formation (Dibblee, 1967), but include a significant fossil flora collected from the sandstone-conglomerate facies of the formation as exposed in the northwestern end of Anaverde Valley (Wallace, 1949; Axelrod, 1950). Axelrod (1950) described 21 species of fossil plants from this area (UCMP Locality P4139) including willow (*Salix*), pine (*Pinus*), aspen (*Populus*), oak (*Quercus*), laurel (*Persea*), sumac (*Rhus*), crab apple (*Peraphyllum*), kidneywood (*Eysenhardtia*), soapberry (*Sapindus*), ceanothus (*Ceanothus*), buckthorn (*Rhamnus*), sycamore (*Platanus*), and serviceberry (*Amelanchier*).

Distribution: The Anaverde Formation is confined to the San Andreas Fault Zone and occurs within the study area along Segment G (MP 5.6 to 5.9), Segment H2 (MP 1.1 to 1.5), and Segment I (MP 7.9 to 8.3).

3.1.5 Pico Formation

General Geology: The Pico Formation in the eastern Ventura Basin is characterized by up to 18,000 feet of deep water marine sedimentary rocks that grade into shallow-marine deposits near the top of the formation (Squires et al., 2006). Kew (1924) named the Pico Formation for exposures in the vicinity of Pico Canyon and described it as of marine origin and consisting of both fine-grained and coarse-grained sandstone with interbeds of conglomerate. According to Squires et al. (2006), the Pico Formation in the eastern Ventura Basin consists of middle to upper bathyal, muddy siltstone deposits that are overlain by wave-dominated-deltaic, sandstone and conglomerate deposits. Oakeshott (1958) divided the Pico Formation in the San Fernando Quadrangle into three members: the Lower Pico Member, which consists of about 700 feet of brownish siltstone, sandstone, and conglomerate that formed in a marine paleoenvironment; the Upper Pico Member, which consists of a few hundred feet of light brownish sandstone and conglomerate that formed in brackish to continental paleoenvironments; and the Sunshine Ranch Member, which consists of 1300 feet of sandy mudstone, sandstone, gravel, and conglomerate with thin white limestone beds that formed in fluvial and lacustrine paleoenvironments. Only the Sunshine Ranch Member has been mapped within the Soledad Basin (Oakeshott, 1958). The Pico Formation in the Valencia area of the Soledad Basin is late Pliocene in age (~3 Ma), based on benthic foraminifera and mollusks (Squires et al., 2006). The Pico Formation conformably overlies the marine Towsley Formation of late Miocene to Pliocene age in the Valencia area of the Soledad Basin (Squires et al., 2006). The Pico Formation is unconformably overlain by the non-marine Saugus Formation of early Pleistocene age (Oakeshott, 1958). However, in the Valencia area, the Pico Formation laterally interfingers with braided-stream deposits of the Saugus Formation (Squires et al., 2006).

Paleontology: The Pico Formation is rich with marine fossils that include abundant encrusting calcareous algae, foraminifera, sponges, marine worms, bryozoans, brachiopods, crabs, barnacles, mollusks, echinoids, sharks, bony fish, pinnipeds, and cetaceans (Eldridge and Arnold, 1907; English, 1914b; Kew, 1924; Kellogg, 1929; Grant and Gale, 1931; Winterer and Durham, 1962; Squires and White, 1983; Groves, 1991a, 1991b; Squires et al., 2006). Terrestrial fossils have also been found in the Pico Formation, such as pine (*Pinus* sp.), oak (*Quercus* sp.), bird, and small cat (Winterer and Durham, 1962; Squires et al., 2006; unpublished UCMP data).

Distribution: The Pico Formation has a very limited distribution in the study area and is confined to Segment K (MP 11.1 to 11.2).

3.1.6 Castaic Formation

General Geology: The Castaic Formation is a marine sedimentary rock unit consisting of 7000 feet of interbedded mudstone, siltstone, sandstone, and conglomerate that formed in a shallow-marine embayment northeast of the San Gabriel Fault at the eastern end of the Ventura Basin (Stanton, 1960, 1966, 1982). Crowell (1954) named the Castaic Formation for the lowest marine unit in the Ridge Basin sedimentary sequence. It is aerially restricted to the southern Ridge Basin and northwestern part of the Soledad Basin (Stanton, 1966; Cooper, 1977). As observed during the windshield survey, the Castaic Formation in the study area consists of thickly bedded gray, fine-grained sandstones interbedded with blue-gray siltstones and shales and red-brown, coarse-grained sandstones. The age of the Castaic Formation is late Miocene to early Pliocene (~6 to 5 Ma), based on benthic foraminifers (McDougall, 1982). The Castaic Formation unconformably overlies strata of the Mint Canyon, Vasquez, and San Francisquito formations (Stanton, 1982). Locally, the Castaic Formation is overlain by strata of the Towsley and Saugus formations and conformably by sedimentary rocks of the Ridge Basin Group (Stanton, 1982).

Paleontology: A diverse assemblage of fossil marine invertebrates, dominated by gastropods and bivalves, has been collected from the Castaic Formation (Skolnick and Arnal, 1959; Stanton, 1960, 1966, 1982; McDougall, 1982; Govean, 1993). Invertebrate fossils include foraminifers, sponges, bryozoans, barnacles, crustaceans, brachiopods, mollusks, and echinoids. Fossil marine vertebrates are rare, but include sharks, rays, bony fish, and marine mammals (Stanton, 1966; Welton and Link, 1982). Other fossils found in the Castaic Formation include fossil wood and leaves (Govean, 1993). During the field survey fossils were observed at several locations within strata of the Castaic Formation and included oxidized plant fragments, carbonized wood, and internal and external molds of marine mollusks.

Distribution: The Castaic Formation is well exposed within the study area and occurs along Segment D (majority of segment between MP 37.5 and 48.2), Segment H2 (MP 17.0 to 17.1), Segment I (MP 29.6 to 31.9), Segment J (majority of the segment between MP 0.0 and 12.0), and Segment K (portions of the segment between MP 0.0 and 1.6).

3.1.7 Towsley Formation

General Geology: The Towsley Formation consists of up to 4,000 feet of petroliferous marine sedimentary rocks exposed on the north slope of the Santa Susana Mountains (Winterer and Durham, 1954). In the eastern part of its area of outcrop in the Elsmere Canyon and Grapevine Canyon area, only the middle portion of the formation is preserved. Here, the Towsley Formation is about 300 feet thick and consists of a lower unit composed of siltstone, sandstone, and conglomerate and an upper unit composed of light brown siltstone and fine sandy siltstone with a thick tongue of coarse-grained sandstone and pebble conglomerate (Kern, 1973). The Towsley Formation is late Miocene to early Pliocene in age (~6 to 5 Ma) and was deposited in the easternmost portion of the Ventura Basin. The formation overlies and interfingers with the Modelo Formation of early late Miocene age and is overlain and interfingers with the Pico Formation of late Pliocene age (Winterer and Durham, 1962; Kern, 1973).

Paleontology: The Towsley Formation contains locally diverse assemblages of marine fossils that include foraminifera, bryozoans, brachiopods, marine worms, crabs, mollusks, echinoids, shark (*Isurus hastalus*), cetacean, sirenian (*Dusisiren jordani*), and walrus (*Imagotaria downsi*) (Eldridge and Arnold, 1907; English, 1914a, 1914b; Kew, 1924; Grant and Gale, 1931; Winterer and Durham, 1954, 1962; Oakeshott, 1958; Kern, 1973; Repenning and Tedford, 1977; Domning, 1978; unpublished LACM data; unpublished UCMP data). The marine deposits exposed in the Elsmere Canyon area are particularly rich in marine fossils (Kern, 1973). Fossils of marine mammals and land mammals have also been found in the Towsley Formation as exposed in Elsmere Canyon and include walrus (cf. *Pontolis* sp.) camel (cf. *Procamelus*) and tapir (English, 1914a; unpublished UCMP data).

Distribution: The Towsley Formation is only exposed along Segment K (MP 9.1 to 11.1, MP 14.3 to 14.4, and MP 15.4 to 15.5) in the study area.

3.1.8 Hungry Valley Formation

General Geology: The Hungry Valley Formation consists of up to 4,500 feet of interbedded conglomerate, sandstone, siltstone, and mudstone strata that formed in braided stream, flood plain, alluvial fan, fluvial-deltaic, and lacustrine paleoenvironments (Crowell, 1982; Link, 2003). The formation crops out in the northern portion of Ridge Basin, west and south of the San Andreas Fault and is divisible into two informal members. The lower member consists of ~3,300 feet of alternating gray, indurated sandstone and mudstone and orange to tan, coarse-grained, loosely consolidated sandstone and conglomerate with interbedded reddish and greenish mudstone. The upper member consists of ~1,300 feet of brown, massive, well indurated conglomerate containing clasts of gneiss, quartz diorite, volcanics, and marble. The Hungry Valley Formation is early Pliocene in age (~5 Ma) and overlies sedimentary rocks of the Ridge Route Formation and Peace Valley Formation. To the east the Hungry Valley Formation directly overlies crystalline basement rocks.

Paleontology: Important paleontological resources are known from the group and include fossil plants (Axelrod 1982), freshwater mollusks (Young 1982), fish (Bell 1973), and terrestrial vertebrates (Miller and Downs 1974 and Welton and Link 1982). The fossil mammal assemblage includes cat, tapir, horse, rhinoceros, llama, camel, pronghorn, elephant, and sloth.

Distribution: The Hungry Valley Formation within the study area only occurs in isolated outcrops along Segment D near the Interstate 5/ State Route 138 interchange (MP 22.4 to 22.7).

3.1.9 Ridge Route Formation

General Geology: The Ridge Route Formation was named by Clements (1929) for outcrops along the old Ridge Route between Templin Highway and Liebre Mountain (Link, 1982). As defined by Link (1982) the Ridge Route Formation consists of up to 30,000 feet of interbedded conglomeratic sandstone, sandstone, and mudstone strata that formed in alluvial fan, braided stream, and deltaic paleoenvironments (Crowell, 1982; Link, 2003). The formation crops-out throughout the eastern portion of Ridge Basin where it is well exposed in roadcuts along the Old Ridge Route. These roadcuts display well stratified sequences of northwest dipping sedimentary rocks consisting of beds of pebble to boulder conglomerate alternating with beds of white to red massive to cross-bedded sandstone. To the west five distinct sandstone and conglomerate tongues of the Ridge Route Formation extend across the basin to interfinger with coarse angular conglomerates of the Violin Breccia (Link, 1982). In ascending order these sandstone tongues include the Marple Canyon Member, Fisher Spring Member, Frenchman Flat member, Piru Gorge member, and Apple Canyon Member of the Ridge Route Formation (Link, 2003). The Ridge Route Formation also interfingers to the west with deltaic and lacustrine sandstones, mudstones, and shales of the Peace Valley Formation. Both formations are late Miocene to early Pliocene in age (~8.4 to 5 Ma) and underlie sedimentary rocks of the Hungry Valley Formation.

Paleontology: Important paleontological resources are known from the various members of the Ridge Route Formation and include fossil plants (Axelrod, 1982), freshwater ostracods (Forester and Brouwers, 1982), mollusks (Young, 1982), and fish (Bell, 1973), and terrestrial vertebrates (Miller and Downs, 1974 and Welton and Link, 1982). The land mammal fossil assemblage includes horse, rhinoceros, and ground sloth.

Distribution: The Ridge Route Formation within the study area crops-out extensively along Segment D near from the Interstate 5/ State Route 138 interchange to Castaic Lake (MP 23.0 to 30.4, MP 30.5 to 30.7, MP 30.8 to 31.9, MP 32.1 to 34.5, and MP 36.4 to 37.5).

3.1.10 Peace Valley Formation

General Geology: The Peace Valley Formation was named by Crowell (1982) for outcrops in Peace Valley along Highway 99 between Templin Highway and Hungry Valley Road (Crowell, 1982). As defined by Link (1982) and Smith (1982) the Peace Valley Formation consists of up to 16,000 feet of interbedded mudstone and shale strata with minor interbeds of sandstone, siltstone, and carbonate that formed in deltaic and lacustrine paleoenvironments (Crowell, 1982; Link, 2003). The formation crops out throughout the western portion of Ridge Basin where it is well exposed in large roadcuts along Interstate 5 south of Coyote Canyon. These roadcuts display well stratified sequences of northwest dipping sedimentary rocks consisting of beds of shale alternating with beds of massive claystone and sandstone. Five distinct shale and siltstone members of the Peace Valley Formation have been recognized that broadly interfinger to the east with the fluvial and deltaic strata of the coeval Ridge Route Formation. In ascending order these members include the Paradise Ranch Member, Osito Canyon Member, Cereza Peak Member, Posey Canyon Member, and Alamos Canyon Member of the Peace Valley Formation (Smith, 1982; Link, 2003). The Peace Valley Formation also interfingers to the west with coarse-grained alluvial fan deposits of the Violin Breccia. The Peace Valley Formations is late Miocene to early Pliocene in age (~8.4 to 5 Ma) and underlies sedimentary rocks of the Hungry Valley Formation.

Paleontology: Important paleontological resources are known from the various members of the Peace Valley Formation and include fossil plants (Axelrod, 1982), freshwater mollusks (Young, 1982) and fish (Bell, 1973; Welton and Link, 1982), and terrestrial vertebrates (Miller and Downs, 1974 and Welton and Link, 1982). The Peace Valley Formation terrestrial vertebrate fossil assemblage includes tortoise, cat, proboscidean, horse, camel, and pronghorn.

Distribution: The Peace Valley Formation within the study area crops-out in isolated patches along Segment D between Posey Canyon and Castaic Lake (MP 30.4 to 30.5, MP 30.7 to 30.8, MP 31.9 to 32.1, and MP 34.5 to 36.4).

3.1.11 Oso Canyon Formation

General Geology: The Oso Canyon Formation consists of up to 5,500 feet of interbedded fanglomerate, conglomerate, sandstone, and siltstone that formed in fluvial paleoenvironments adjacent to a shallow marine embayment (Dibblee, 1967; Crowell, 2003). The formation is exposed at the western end of the Antelope Valley, where it has been deformed by faulting associated with the San Andreas Fault Zone (Dibblee, 1967). Fanglomerates in the formation consist of poorly sorted massive beds of subrounded pebbles, cobbles and boulders derived from granitic and volcanic igneous rocks exposed in the surrounding mountains. The conglomerates, sandstones, and siltstones are well bedded and interfinger to the west with sandstones and shales of the marine Quail Lake Formation (Dibblee, 1967; Crowell, 2003). The Oso Canyon Formation is considered to be late Miocene in age (~10 Ma) based on its stratigraphic relationships with the Quail Lake Formation (Dibblee, 1967).

Paleontology: Although fossils have not been reported from the Oso Canyon Formation, its sedimentary origin and fluvial paleoenvironments indicate a strong but unproven potential for producing fossil remains.

Distribution: The Oso Canyon Formation within the study area only occurs in isolated outcrops along Segment D (MP 16.7 to 17.2 and MP 17.8 to 18.1).

3.1.12 Quail Lake Formation

General Geology: The Quail Lake Formation (Santa Margarita Formation of Wiese, 1950) consists of 1,000 feet of gray white, medium- to coarse-grained sandstones and dark brown to black thinly bedded shales that formed in nearshore marine paleoenvironments in the eastern Ventura Basin (Dibblee, 1967). Sandstones are regularly bedded and grade laterally into pebble and cobble conglomerates containing clasts of granitic and volcanic igneous composition (Crowell, 1952). To the northeast, the conglomeratic sandstones of the Quail Lake Formation grade into fluvial red and green sandstones, siltstones and fanglomerates of the Oso Canyon Formation. The Quail Lake Formation is thought to be late Miocene in age (~10 Ma) based on contained marine molluscan and echinoid fossils (Wiese, 1950; Crowell, 1952).

Paleontology: The Quail Lake Formation is one of the few marine rock units exposed in the Mojave Desert. Wiese (1950) reported molluscan fossils (osysters, scallops and moon snails) and echinoderms (sand dollars), as well as marine vertebrates (sharks) from the formation. Of special note is the common occurrence of the giant oyster, *Crassostrea titan*, a species characteristic of the Santa Margarita Formation in the San Joaquin Valley. Crowell (1952) reported similar fossils from Quail Lake Formation including additional species of marine clams and snails.

Distribution: The Quail Lake Formation in the study area is confined to the portion of Segment D adjacent to Quail Lake (MP 17.2 to 17.5).

3.1.13 Monterey/Modelo Formation

General Geology: The Monterey Formation (Modelo Formation of Oakeshott, 1958; Winterer and Durham, 1962) consists of 500 feet of tan to gray diatomaceous shale, silty shale, sandstone, and conglomerate that formed in open-marine paleoenvironments in the eastern Ventura Basin (Dibblee and Ehrenspeck, 1991). A basal, cobble conglomerate a few feet thick lies at the base of the Monterey/Modelo Formation in the Soledad Basin (Oakeshott, 1958). The majority of the remaining formation consists of fine- to coarse-grained sandstone with interbedded shale near the top of the formation (Oakeshott, 1958). The Monterey/Modelo Formation is middle to early late Miocene in age (~13 to 10 Ma) in the eastern Ventura Basin (Oakeshott, 1958). The Monterey/Modelo Formation overlies the non-marine Mint Canyon Formation of middle Miocene age and is in turn, overlain by the marine Towsley Formation of late Miocene to early Pliocene age (Oakeshott, 1958).

Paleontology: The Monterey/Modelo Formation in the eastern part of the Ventura Basin, as well as in the Soledad, and Los Angeles basins contains locally abundant marine fossils including foraminifers, bivalve mollusks (e.g., *Delectopecten* sp.), gastropod mollusks, echinoids, fish, and cetaceans (*Mixocetus elysius*, *Pithanodelphis nasalis*) (Kellogg, 1934; Daviess, 1942; Winterer and Durham, 1962; Bussino and Barnes, 1984; Barnes, 1985). Land vertebrates, such as birds (*Phalacrocorax femoralis*), have also been recovered from this rock unit in the study area (Miller, 1929).

Distribution: The Monterey/Modelo Formation in the study area is confined to the southern terminus of Segment K (MP 14.4 to 15.4).

3.1.14 Mint Canyon Formation

General Geology: The Mint Canyon Formation consists of 4,500 feet of claystone, siltstone, conglomeratic sandstone, conglomerate, and sedimentary breccia that formed in deltaic, fluvial, and lacustrine paleoenvironments (Oakeshott, 1950, 1958; Winterer and Durham, 1962; Hall, 2007; Kew, 1923). The formation is divided into a “Lower variegated member” and an “Upper gray member” that both contain vertebrate faunas of different ages (Durham et al., 1954). Sediments in the Mint Canyon Formation were derived from the Sierra Pelona, San Gabriel Mountains, and Mojave Desert and deposited in broad valleys, flood plains, and small intermittent lakes across folded and faulted strata of the Vasquez Formation and the marginal crystalline rocks of the Soledad Basin (Oakeshott, 1958). Although the Mint

Canyon Formation is only present within the eastern Ventura and Soledad basins, the same clast types within the Caliente Formation indicate that the latter formation should be considered a part of the Mint Canyon Formation. This interpretation suggests that the Caliente Formation has been offset from the Mint Canyon Formation by at least 70 km of right-lateral displacement along the San Gabriel Fault (Ehlert, 2003). As observed during the field survey, the Mint Canyon Formation in the study area consists of thickly interbedded, light gray to pinkish strata including pebble conglomerates, coarse-grained pebbly sandstones, and massive sandy siltstones. The Mint Canyon Formation is most likely middle to late Miocene in age (14 to 11 Ma), based on fossil land mammals that indicate Barstovian to Clarendonian North American land mammal ages. The Mint Canyon Formation unconformably overlies strata of the non-marine Tick Canyon Formation of early Miocene age. It is unconformably overlain by the marine Monterey/Modelo Formation of middle to early late Miocene age (Oakeshott, 1958), the Castaic Formation of late Miocene to early Pliocene age (Dibblee, 1996a), and the Saugus Formation of late Pliocene to early Pleistocene age (Dibblee, 1996b).

Paleontology: The Mint Canyon Formation has produced large and diverse fossil assemblages of plants (Axelrod, 1940; Mount, 1971), freshwater mollusks and ostracods (Kew, 1924; Oakeshott, 1958; Mount, 1971), turtle (*Clemmys* sp.; Maxson, 1930), and land mammals that include rabbit, dog, peccary (*Prosthennops* sp.), rhinoceros, camel (*Alticamulus* sp.), pronghorn antelope (*Merycodus necatus*), three genera of horse (*Merychippus intermontanus*, *M. sumani*, *Protohippus* sp., *Hipparion mohavense*, *Pliohippus* sp. cf. *P. fossulatus*), and mastodon (Kew, 1924; Maxson, 1928, 1930; Stirton, 1933, 1939; Savage et al., 1954; Kelly, 1998). Thin lacustrine and fluviatile interbeds contain freshwater gastropods (*Paludestrina imitator*, cf. *Helminthoglypta* sp.), bivalves (*Amnicola* sp.), and ostracods (Kew, 1924; Oakeshott, 1958; Mount, 1971). Local tuff beds contain fossil leaves that represent an oak-savanna community whose nearest related modern equivalent species now occur in southern California, southern Arizona, and northern Mexico (Axelrod, 1940; Wallace, 1940). These fossil leaves were derived from at least four habitats: lake-border and riparian, savanna, woodland, and chaparral (Axelrod, 1940). Although no fossils were observed in Mint Canyon Formation strata during the field survey, the results of the record search indicate several recorded fossil collecting localities (LACM and UCMP) in the Vasquez and Bouquet canyon portions of the study area.

Distribution: The Mint Canyon Formation within the study area occurs along Segment D (MP 47.4 to 47.5 and MP 47.6 to 47.8), Segment G (MP 20.8 to 21.2), Segment H2 (MP 15.4 to 17.0), Segment I (portions of the Segment between MP 24.6 and 31.6), Segment J (MP 0.2 to 0.6), and Segment K (MP 0.2 to 1.1).

3.1.15 Tick Canyon Formation

General Geology: The Tick Canyon Formation consists of 600 feet of reddish sandstone, siltstone, and claystone, as well as gray, tan, and reddish conglomerate that formed in fluvial and lacustrine paleoenvironments (Oakeshott, 1958). Jahns (1939) designated the lowest few hundred feet of the Mint Canyon Formation as the "Tick Canyon Formation" on the basis of a fossil vertebrate fauna that was distinctly older than the faunas of the overlying Mint Canyon strata. The base of the Tick Canyon Formation consists of 100 feet of grayish to brown fanglomerate that contains poorly sorted and loosely consolidated fragments of various sizes of up to a foot or more in diameter (Oakeshott, 1958). Most of the clasts consist of granite, vasquez-like basalt, and anorthosite (Oakeshott, 1958). The basal fanglomerate is overlain by reddish sandstone, mudstone, and siltstone with some interbedded yellowish and green siltstone and thin interbeds of conglomerate (Oakeshott, 1958). As observed during the windshield survey, the Tick Canyon Formation in the study area consists of pinkish red sandstones and siltstones. The Tick Canyon Formation is mostly early Miocene in age (late Arikareean to Hemingfordian North American land mammal ages; 24.15 to 15.90 Ma), based on the fossil land mammals (Hall, 2007). The Tick Canyon Formation unconformably overlies the non-marine Vasquez Formation of Oligocene to early Miocene age and is unconformably overlain by the non-marine Mint Canyon Formation of middle Miocene age (Jahns, 1939).

Paleontology: Fossils are rare in the Tick Canyon Formation, but include important land mammal fossils, such as heteromyid rodents, rabbits (*Archaeolagus acaricolus*), slender-limbed oreodonts (*Merychyus calaminthus*), camelids (*Miolabis californicus*), and horses (*Parahippus maxsoni*) (Jahns, 1939, 1940; Reeder, 1960; Whistler, 1967). A fossil hawk (*Miohierax stocki*) has also been recovered from strata of the Tick Canyon Formation (Howard, 1944). Although no fossils were observed in Tick Canyon Formation strata during the windshield survey, the results of the record search indicate several recorded fossil collecting localities (LACM) in the Vasquez Canyon portion of the study area.

Distribution: The Tick Canyon Formation within the study area only occurs along Segment I (MP 24.4 to 24.6).

3.1.16 Vasquez Formation

General Geology: The Vasquez Formation consists of 8,800 feet of terrestrial sedimentary and volcanic rocks of Oligocene to early Miocene age (Oakeshott, 1958; Dibblee, 1967; Hendrix and Ingersoll, 1987). Sharp (1936) named and described these rocks as the "Vasquez series," after the very prominent outcrops at Vasquez Rock in Aqua Dulce. The Vasquez Formation represents both the earliest and the thickest sedimentary accumulation within the Tertiary Soledad Basin (Hendrix and Ingersoll, 1987; Hendrix, 1993). Included sedimentary rocks consist of interbedded sandstones, shales, mudstones, siltstones, breccias, and conglomerates deposited in alluvial fan, fluvial, and lacustrine paleoenvironments (Oakeshott, 1958; Hendrix and Ingersoll, 1987; Hall, 2007). Very coarse-grained clastic sediments, with marked angularity of grains, and indistinct bedding, locally derived from the underlying crystalline rocks, make up a large part of the formation; although well-bedded, indurated, coarse-grained sandstone and thin bedded, lake-deposited shale and siltstone are locally prominent (Oakeshott, 1958). The base of the Vasquez Formation consists of about 40 feet of reddish-brown conglomerate. The basal conglomerate is overlain by about 400 feet of reddish-brown, coarse-gained sandstone with shale interbeds and minor lenses of conglomerate (Oakeshott, 1958). These strata are overlain by about 60 feet of very coarse fanglomerate, which in turn is overlain by up to 3800 feet of basalt flows and sills. The basalt flows are overlain by 4,500 feet of coarse-grained sandstone with conglomerate and shale interbeds (Oakeshott, 1958). The formation also contains volcanic flows of black and reddish vesicular basalt and andesite, beds of purplish breccia, and minor beds of lithic tuff (Oakeshott, 1958). The Vasquez Formation was mildly folded, faulted, and eroded before sedimentary rocks of the overlying Tick Canyon Formation were deposited (Oakeshott, 1958). As observed during the windshield survey, the Vasquez Formation in the study area consists of deep purplish red, very well indurated, coarse-grained sandstones and pebble conglomerates. Radiometric dates from basalt flows provide an age of 25.6 to 23.6 Ma (late Oligocene to early Miocene), which is consistent with biochronological age estimates based on rare land mammal fossils (Arikareean to Hemingfordian; 29 to 22.5 Ma) (Hall, 2007). The Vasquez Formation nonconformably overlies anorthosite and gneiss of Precambrian age and is unconformably overlain by the non-marine Tick Canyon Formation of early Miocene age.

Paleontology: Fossils are extremely rare in the Vasquez Formation; but, according to Hall (2007), at least one fossil of the extinct horse *Merychippus* has been found in the formation. However, no reports were found of this purported discovery in the peer-reviewed literature. No fossils were observed in exposures of this rock unit during the windshield survey and there are no recorded fossil collecting localities reported from this rock unit in the institutional record search.

General Geology: The Vasquez Formation within the study area only occurs along Segment G (MP 13.8 to 13.9).

3.1.17 San Francisquito Formation

Introduction: The San Francisquito Formation consists of over 13,000 feet of shale, sandstone, and conglomerate that formed in a variety of marine settings including sandy intertidal, subtidal, continental shelf, slope, and submarine-fan paleoenvironments (Johnson, 1952; Dibblee, 1967; Kooser, 1980, 1982;

Kirby, 1991). Dibblee (1967) formally named, described, and mapped the San Francisquito Formation based on good exposures of this rock unit in San Francisquito Canyon. Sage (1975), Kooser (1980, 1982), and Kirby (1991) later provided more detailed stratigraphic descriptions of the San Francisquito Formation. As observed during the windshield survey, the San Francisquito Formation in the study area consists of well indurated, light gray to brown, medium-grained, gravelly sandstones, as well as interbedded sequences of thinly bedded fine-grained sandstones and shales. The San Francisquito Formation ranges in age from late Cretaceous (Maastrichtian, ~70 Ma) to Paleocene (~60 Ma) (Kooser, 1980, 1982; Saul, 1983; Kirby, 1991). Kirby (1991) determined that the San Francisquito Formation is conformable across the Cretaceous/Tertiary boundary at Warm Springs Mountain. The San Francisquito Formation nonconformably overlies granodiorite and gneiss of Mesozoic age and locally is unconformably overlain by strata of the Vasquez Formation, the Mint Canyon Formation, and/or the Castaic Formation.

Paleontology: The San Francisquito Formation in the San Francisquito Canyon area contains very diverse fossil assemblages of shallow-marine invertebrate fossils, which includes corals, brachiopods, gastropods, bivalves, ammonites (*Diplomoceras* sp.), and sharks (Dickerson, 1914; Kooser, 1980, 1982; Saul, 1983; Popenoe and Saul, 1987; Squires et al., 1989; Kirby, 1991; Kirby and Saul, 1995; Squires and Saul, 2006, 2007). Elsewhere in southern California, near Cajon Pass, a fossil plesiosaur has been found in the San Francisquito Formation (Kooser, 1985; Lucas and Reynolds, 1993). During the windshield survey trace fossils were observed at several locations within strata of the San Francisquito Formation and included cylindrical burrows made by infaunal marine invertebrates. The institutional record search found numerous recorded fossil collecting localities (LACM) in the Study Area.

Distribution: The San Francisquito Formation within the study area only occurs along Segment G (MP 12.4 to 13.8).

3.1.18 Plutonic Igneous Rocks

General Geology: Plutonic igneous rocks of Mesozoic and Paleozoic age occur in several areas in the western San Gabriel Mountains region. Plutonic rocks in the study area include granodiorite and granite. The granodiorite consists of gray, medium- to coarse-grained plutonic rocks with closely related variants ranging from quartz diorite to granite (Oakeshott, 1958). The granitic rocks consist predominantly of tan to pink, fine- to medium-grained, biotite-muscovite granite with certain portions porphyritic, others pegmatitic and aplitic, and much of it gneissoid (Oakeshott, 1958). These rocks probably underlie the entire Soledad Basin north and northwest of the Soledad and Pole Canyon fault zones (Oakeshott, 1958). The plutonic rocks in the study area are believed to be related to and essentially correlative with similar rocks of late Jurassic to Cretaceous age elsewhere in the Transverse and Peninsular ranges, the Mojave Desert, and the Sierra Nevada mountain range (Oakeshott, 1958).

Paleontology: Because of the extremely high temperatures and pressures associated with the magmatic origin of the plutonic igneous rocks in the study area, no fossils are expected in these rocks.

Distribution: Plutonic igneous rocks within the study area occur along Segment G (major portions of the Segment between MP 4.2 and 11.8), Segment H1 (MP 2.2 to 2.6), Segment H2 (MP 1.9 to 5.4), and Segment I (MP 4.7 to 5.1, MP 18.4 to 18.9, and MP 19.3 to 21.5).

3.1.19 Mendenhall Gneiss

General Geology: The Mendenhall Gneiss is a blue, quartz-feldspar-rich gneiss that has been intruded by anorthosite-gabbro rocks, all of Precambrian age (Oakeshott, 1958). Oakeshott (1958) named and described the Mendenhall Gneiss after the Mendenhall Peak, where it is well exposed. It is overlain nonconformably by the Mint Canyon Formation of early Miocene age in Sand Canyon (Oakeshott, 1958).

Paleontology: No fossils are expected in the gneiss because of the extreme temperatures and pressures associated with the metamorphic origin of these rocks.

Distribution: Rocks mapped as gneiss occur along Segment G (MP 6.4 to 7.7, MP 10.7 to 10.9, and MP 11.8 to 12.3) and Segment I (MP 18.2 to 18.4 and MP 21.5 to 24.4).

3.1.20 Pelona Schist

General Geology: The Pelona Schist is primarily composed of about 7,500 feet of bluish-gray schist that was metamorphosed from clastic and pryoclastic sedimentary rocks (Muehlberger and Stanton Hill, 1958; Oakeshott, 1958; Dibblee, 1967). Hershey (1902) named and described the metamorphic rocks that crop out along the Sierra Pelona Ridge as the "Pelona schist series" (Oakeshott, 1958). The most common rock types include greenish-gray mica-chlorite-albite schist, green actinolite-albite schist with albite porphyroblasts, quartz-biotite schist, quartzite, and actinolite-talc schist (Oakeshott, 1958). These rocks are strongly foliated and contain minerals that are characteristic of the low temperature green-schist facies of metamorphism (Oakeshott, 1958). The Pelona Schist is Precambrian in age (Muehlberger and Stanton Hill, 1958).

Paleontology: No fossils are expected in the Pelona Schist because of the extreme temperatures and pressures associated with the metamorphic history of these rocks.

Distribution: Outcrops of the Pelona Schist occur occur over large portions of Segment G (MP 5.1 to 5.4, MP 14.0-16.1, and MP 17.6 to 19.2), Segment H2 (MP 0.1 to 0.8 and MP 5.4 to 15.4), and Segment I (MP 5.1 to 7.8, 8.4 to 14.8, and 15.0 to 18.2).

4.0 INVENTORY METHODS

The goal of the paleontological resources inventory was to identify, describe, and map existing paleontological resources within the study area and to evaluate the level of resource significance for each. The inventory relied on a review of relevant published geologic reports (Kew, 1924; Dibblee, 1967; and Crowell, 2003), privately published geologic mapping from the Dibblee Foundation (Dibblee and Ehrenspeck 1991, 1996a. 1996b, 1996c, 1997a, 1997b, 1997c; and Dibblee and Minch, 2002); unpublished environmental technical reports (Hulbert, 2004), and museum paleontological site records (Natural History Museum of Los Angeles County, Invertebrate Paleontology Section-LACMIP, San Diego Natural History Museum-SDNHM, and University of California, Museum of Paleontology-UCMP). This approach was followed in recognition of the direct relationship between paleontological resources and the geologic formations within which they occur. Knowing the geology of a particular area and the documented fossil productivity of the formations occurring in that area, it is possible to make reasonable predictions about where fossils will, or will not, be encountered.

The results of the literature, institutional record, and field survey portions of the inventory were incorporated with GIS layers of Project milepost delineations to estimate the linear coverage of individual geologic formations along specific Project segments. These data were then summarized in a paleontological resource table (Appendix A). Following this, paleontological resource sensitivity values were determined for each formation and the relative resource value of each Project segment quantified based on the linear distribution (i.e., mileage) as summarized in Appendix A.

Windshield surveys were conducted during September and October 2008 along the southern portion of the study area (segments F, G, H, and I, as well as portions of B, E, and K) to verify geologic mapping and results of the literature and previous institutional record surveys. The survey was primarily conducted along LADWP access roads, but also involved some portions of public roads. During the survey work, selected bedrock outcrops were examined to determine paleontological sensitivity of geologic rock units occurring in the study area.

The proposed BRRTP area of potential physical disturbance is defined as land within 250 feet of the assumed centerlines of proposed and existing transmission lines; land likely to be disturbed during construction of the new Haskell Canyon Switching Station; plus ancillary areas. Ancillary areas, most of which have not yet been defined, include, but are not limited to, staging areas, access and spur roads, and pulling and tensioning sites.

5.0 AFFECTED ENVIRONMENT

The affected environment as it pertains to paleontological resources includes not only actual fossil remains collected at specific locations, but also the collecting localities themselves, as well as the geologic formations containing those localities. In this light, a particular geologic rock unit (i.e., formation) can be considered to represent a proxy for all possible paleontological resources (i.e., fossils) entombed and preserved in that formation. Further, although fossils may not have been previously collected from a geologic formation in a given area, the fact that fossils have been recovered from that same formation in other areas where it crops-out is taken as an indication of the potential of that formation to preserve similar fossils wherever it occurs.

6.0 IMPACT ASSESSMENT

Environmental impacts can be positive (beneficial) or negative (adverse) as a primary result of an action (direct) or as a secondary result of an action (indirect), and can be permanent or long-lasting (long-term), or temporary and of short duration (short-term). Impacts can vary in degree or magnitude from no change, to slightly discernible change, to a complete change in the environmental condition or system (intensity). Impact significance is determined by judging whether the action exceeds specific thresholds.

For paleontological resources, earthwork operations (e.g., mass grading, trenching, and boreholes) that cut into sedimentary rock units containing, or potentially containing, fossils would impact those same fossils as they are unearthed. These excavation-related direct impacts can be beneficial by creating short-term opportunities to recover previously buried and undiscovered fossils. Conversely, these impacts can be adverse by causing the permanent destruction of the same previously buried and undiscovered fossils. Impact magnitude is directly correlated with the scale of the proposed earthwork (e.g., large scale mass grading operations to construct the new switching station will create a permanent and complete change to a fossil-bearing stratum [rock layer] that is graded away, while small scale and very localized footing boreholes would create a permanent but slight change to a fossil-bearing stratum that is being bored through). Construction of new access roads has the possibility to create indirect beneficial impacts by increasing access for paleontologists to previously unexplored areas where new fossil discoveries can be made. On the other hand, these same access roads can create indirect adverse impacts by increasing opportunities for unregulated “pot hunting” of potentially significant paleontological resources.

6.1 SIGNIFICANCE CRITERIA

The proposed Project has been evaluated with respect to its potential impacts on paleontological resources. Paleontological resources that may be affected by construction of the BRRTP are confined to those geologic rock units consisting of sedimentary rocks of late Mesozoic and Cenozoic age. Assessment of the significance of potential Project impacts on these resources is based on the resource sensitivity of individual rock units as well as the proposed action (e.g., grading of new access roads vs. rehabilitation of existing access roads; excavation of building pads for the new switching station vs. rehabilitation of the existing switching station; excavation of foundation pads for new transmission structures vs. reconductoring of existing structures; and excavation of new pulling stations vs. passive suspension of transmission lines between adjacent transmission structures).

Impact or ground disturbance has been modeled for the BRRTP using a series of Ground Disturbance Categories (GDC) that include the following: GDC 1 – ground disturbance associated with use of existing improved roads or agricultural land; GDC 2 – ground disturbance associated with use of existing access roads that require improvements; GDC 3 - ground disturbance associated with construction of a new road on flat terrain (0-10% slope); GDC 4 - ground disturbance associated with construction of a new access road on sloping terrain (10-20% slope); GDC 5 - ground disturbance associated with construction of a new access road on steep terrain (20-30% slope); GDC 6 - ground disturbance associated with construction of a new access road on very steep terrain (>30% slope); and GDC H - ground disturbance associated with use of helicopters to supply construction crews and transport tower components (see Appendix A).

6.2 SENSITIVITY VALUES

The following levels of paleontological resource sensitivity are rated for individual formations and recognize the important relationship between fossils and the geologic formations within which they are entombed. These sensitivity values are summarized for each Project segment in Appendix A.

Maximum Sensitivity: Maximum sensitivity is assigned to geologic formations known to contain paleontological localities with rare, well-preserved, critical fossil materials for stratigraphic or paleoenvironmental interpretation, and fossils providing important information about the paleobiology and evolutionary history (phylogeny) of animal and plant groups. Generally speaking, highly sensitive formations produce vertebrate fossil remains or are considered to have the potential to produce such remains. The following rock units known to occur within the study area are assigned a maximum paleontological resource sensitivity:

- Saugus Formation
- Anaverde Formation
- Pico Formation
- Hungry Valley Formation
- Peace Valley Formation
- Ridge Route Formation
- Castaic Formation
- Quail Lake Formation
- Towsley Formation
- Monterey/ Modelo Formation
- Mint Canyon Formation
- Tick Canyon Formation
- San Francisquito Formation

Major/Undetermined Sensitivity: Major/undetermined sensitivity is assigned to geologic formations known to contain paleontological localities with moderately well- to poorly-preserved, common elsewhere, or stratigraphically long-ranging fossil material. The major sensitivity category is also applied to geologic formations that are judged to have a strong, but unproven potential for producing important fossil remains. The following rock units known to occur within the study area are assigned a major/undetermined paleontological resource sensitivity:

- Older alluvium
- Oso Canyon Formation
- Vasquez Formation

Minor Sensitivity: Minor sensitivity is assigned to geologic formations that, based on their relatively youthful age and/or high-energy depositional history, are judged unlikely to produce important fossil remains. Typically, minor sensitivity formations produce poorly-preserved invertebrate fossil remains in low abundance. Due to the young age and oxidized nature of the Quaternary alluvial deposits mapped within the study area, these surficial sedimentary deposits are considered to have little potential to yield scientifically significant fossils and are assigned a minor resource sensitivity.

Zero Sensitivity: Zero sensitivity is assigned to geologic formations that are entirely igneous in origin or have undergone high grade metamorphism, and therefore have no potential for producing fossil remains. The following rock units known to occur within the study area have no paleontological resource sensitivity:

- Plutonic igneous rocks
- Gneissic rocks
- Pelona Schist

6.3 IMPACT LEVELS

The following definitions have been provided regarding significance criteria used for evaluation of impacts to paleontological resources. Significance is defined as a measure of probable adverse response of a resource to direct and indirect impacts associated with the construction, operation, and maintenance of Project components. It is important to emphasize that determination of impact significance considers both the resource sensitivity of an area as well as the level of ground disturbance proposed for that area. For paleontological resources, these factors are summarized below in Table 6-1, which categorizes initial impacts as either high, moderate, or low, based upon the following general characteristics.

High – A high level of impact to paleontological resources would result if the construction, operation, or maintenance of the proposed Project would cause a significant or substantial ground disturbance (GDC 4 and greater) or other adverse change to paleontological resources defined as having maximum sensitivity.

Moderate – A moderate impact to paleontological resources would result if the construction, operation, or maintenance of the proposed Project would potentially cause ground disturbance (GDC 3 or greater) or other adverse change to the condition of paleontological resources defined as having major/undetermined sensitivity. Moderate impacts would also occur where construction, operation, or maintenance of the proposed Project would result in minor or minimal ground disturbance (GDCs 2 and 3) or other adverse change at or near paleontological resources defined as maximum sensitivity.

Low –A low impact to paleontological resources would result if the construction, operation, or maintenance of the proposed Project would potentially cause any amount of ground disturbance or other adverse changes to paleontological resources that have been defined as having minor sensitivity.

No Identifiable Impact - No identifiable impact would be indicated where no measurable or suspected adverse impact would occur to any paleontological resources. These include areas that are underlain by igneous or metamorphic rock units.

TABLE 6-1. IMPACT MATRIX COMPARING PALEONTOLOGICAL RESOURCE SENSITIVITY AND GROUND DISTURBANCE.

	Ground Disturbance Categories						
Resource Sensitivity	1	2	3	4	5	6	H
Maximum	Low	Moderate	Moderate	High	High	High	High
Major/Undetermined	Low	Low	Moderate	Moderate	Moderate	Moderate	Moderate
Minor	Low	Low	Low	Low	Low	Low	Low
Zero	No	No	No	No	No	No	No

6.4 MITIGATION PLANNING

As summarized above and itemized in Table 6-1, construction of the Project would result in high and moderate levels of impact to paleontological resources with Major/Undetermined and Maximum resource sensitivity. These significant initial impacts can be reduced to a low residual level through the sequential implementation of the following mitigation measures:

PR-1: A qualified paleontologist/principal investigator shall be retained by LADWP to develop and implement a paleontological resource mitigation plan (PMTP). A qualified paleontologist is defined as an individual with a MS or Ph.D. in paleontology or geology who is experienced with paleontological procedures and techniques, who is knowledgeable in the geology and paleontology of the Project area, and who has worked as a paleontological mitigation project supervisor for at least one year. The qualified paleontologist shall attend relevant pre-construction meetings to consult with grading and excavation contractors concerning excavation schedules, paleontological field techniques, and safety issues. The PMTP shall be based on Society of Vertebrate Paleontology (SVP) guidelines and meet all regulatory requirements. The PMTP shall identify construction impact areas of major/undetermined to maximum sensitivity for encountering significant resources and the depths at which those resources are likely to be encountered. Preconstruction surveys of these areas shall be conducted prior to commencement of construction activities. The PMTP shall outline a coordination strategy to ensure that a qualified paleontological monitor would conduct full-time monitoring of all ground disturbance in sedimentary rocks determined to have a major/undetermined to maximum sensitivity. Sedimentary rocks of low, marginal, and undetermined sensitivity shall be monitored on a part-time basis (as determined by the qualified paleontologist). Geologic rock units with zero sensitivity would not require paleontological monitoring. The PMTP shall detail the significance criteria to be used to determine which resources would be avoided or recovered for their data potential. The PMTP shall also detail methods of recovery, preparation and analysis of specimens, final curation of specimens at a federally accredited repository, data analysis, and reporting. The PMTP shall specify that all paleontological work undertaken by the Applicant on public land shall be carried out by qualified paleontologists with the appropriate current permits, including, but not limited to a Paleontological Resources Use Permit (for work on public lands administered by BLM). Notices to proceed would be issued by the BLM, CPUC, and other agencies with jurisdiction, following approval of the PMTP.

PR-2: A paleontological monitor shall be retained on a full-time basis to monitor Project-related construction excavations (e.g., road grading, switching station mass grading, and tower footing boreholes and pad construction) in areas underlain by paleontological resources of maximum and major sensitivity. Project-related construction excavations in areas underlain by paleontological resources of undetermined sensitivity shall be monitored on a part-time basis, while Project-related construction excavations in areas underlain by paleontological resources of minor or zero sensitivity would not require any monitoring. A qualified paleontological monitor shall have a B.S. in geology or paleontology and have at least one year experience in the collection and salvage of fossil materials. The paleontological monitor shall work under the direction of the qualified paleontologist.

PR-3: Prior to the initiation of construction or ground-disturbing activities, all construction personnel shall be trained regarding the recognition of possible subsurface paleontological resources and protection of all paleontological resources during construction. Training shall inform all construction personnel of the procedures to be followed upon the discovery of paleontological resources. All personnel shall be instructed that unauthorized collection or disturbance of protected fossils on or off the right-of-way will not be allowed.

PR-4: When fossils are discovered, the qualified paleontologist (or paleontological monitor) shall recover them. In most cases fossil salvage activities can be completed in a short period of time. However, some fossil specimens (such as a complete large mammal skeleton) may require an extended salvage period. In these instances the paleontologist shall be allowed to temporarily direct, divert, or halt earthwork to allow recovery of fossil remains in a timely manner. At each fossil discovery site field data forms shall be prepared to document the geographic, geologic, stratigraphic, and taphonomic aspects of the discovery. Because of the potential for the recovering of small fossil remains, such as isolated mammal teeth, as determined by a qualified paleontologist, it may be necessary to collect bulk samples (up to 6,000 pounds) of sedimentary rock matrix. This bulk matrix sample shall then be tested by screenwashing a 200 pound subsample to determine the presence and relative abundance of identifiable microfossils. If positive results are obtained, the entire sample shall be screenwashed.

PR-5: To the extent feasible, fossil remains collected during monitoring and salvage shall be cleaned, repaired, sorted, and cataloged as part of the mitigation program. Prepared fossils, along with copies of all pertinent field notes, photos, and maps, shall be deposited in a federally accredited repository for both vertebrate and invertebrate fossils such as the Natural History Museum of Los Angeles County or the Museum of Paleontology at the University of California, Berkeley. Funds for curation will be the responsibility of LADWP. The Project qualified paleontologist shall be authorized to submit fossils with accompanying deeds of gift for curation on behalf of LADWP. Donation of the fossils shall be accompanied by financial support for initial specimen storage (costs vary for individual institutions). A final summary report shall be completed that outlines the results of the mitigation program. This report shall include discussions of the methods used, stratigraphic section(s) exposed, fossils collected, and significance of recovered fossils.

7.0 IMPACT RESULTS

Table 7.1 summarize the ROW mileage for initial impacts and paleontological resource sensitivity in regards to the Project components (new 230 kV transmission line [segments], new 230 kV circuit, reconductoring of the existing transmission line, new switching station, and expansion of existing switching station) and land management agency (BLM, NFS) and will be discussed further in the following sections.

7.1 NEW 230 KV TRANSMISSION LINE

7.1.1 Segment A

Construction of the new 230 kV transmission line along Segment A would traverse 13.2 miles of sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity; impacts are not significant and would not require mitigation.

7.1.2 Segment B

Construction of the new 230 kV transmission line along Segment B would traverse 26.5 miles of sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity; impacts are not significant and would not require mitigation.

7.1.3 Segment C

Construction of the new 230 kV transmission line along Segment C would traverse 21.7 miles of sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity; impacts are not significant and would not require mitigation.

7.1.4 Segment D

Construction of the new 230 kV transmission line along Segment D would traverse 43 miles of sedimentary deposits defined as having minor, major/undetermined, and maximum sensitivity (see Table 7.1 and Appendix A). In addition, 0.9 of a mile of this segment crosses areas underlain by plutonic igneous rocks with zero resource sensitivity. 21.3 miles of Segment D traverse sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity; impacts are not significant and would not require mitigation. 1.1 miles of this segment cross sedimentary deposits of the Oso Canyon Formation. This rock unit was deposited during the late Miocene (~10 Ma) and, although not proven to contain fossils, its sedimentary origin and fluvial paleoenvironments indicate a strong but unproven (i.e., undetermined) potential for producing fossil remains. Ground disturbance estimates for these areas of undetermined sensitivity are only levels 1 and 2, indicating low initial impacts and thus not requiring mitigation. 20.6 miles of Segment D traverse sedimentary deposits of the Saugus Formation (fluvial and alluvial fan deposits of late Pliocene to early Pleistocene age; ~3 to 1.5 Ma), the Hungry Valley Formation (fluvial, deltaic, and lacustrine deposits of early Pliocene age; ~5 Ma), the Castaic Formation (marine sandstones of late Miocene to early Pliocene age; ~6 to 5 Ma), the Ridge Route Formation (alluvial fan, fluvial, and deltaic deposits of late Miocene to early Pliocene age; ~8.4 to 5 Ma), the Peace Valley Formation (deltaic and lacustrine deposits of late Miocene to early Pliocene age; ~8.4 to 5 Ma), the Quail Lake Formation (marine sandstones of late Miocene age; ~10 Ma), and the Mint Canyon Formation (deltaic, fluvial, and lacustrine deposits of middle to late Miocene age; ~14 to 11. Ma). All of these rock units are known to produce significant paleontological resources and are defined as having maximum sensitivity. Ground disturbance estimates for certain areas of maximum sensitivity are only level 1, indicating low initial impacts and no required mitigation. However, there are also areas of maximum sensitivity where ground disturbance estimates range from level 2 to 6 (i.e., moderate to high initial impacts) and these impacts would require mitigation. All of these potential moderate to high impacts can be reduced to low residual impacts through adoption of appropriate mitigation measures (see Mitigation Measures PR-1 through PR-5).

7.1.5 Segment E

Construction of the new 230 kV transmission line along Segment E would traverse 9.7 miles of sedimentary deposits defined as having minor and major/undetermined sensitivity (see Table 7-1 and Appendix A). In addition, 0.8 of a mile of this segment crosses areas underlain by plutonic igneous rocks with zero resource sensitivity. 7.5 miles of Segment E traverses sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity; impacts are not significant and would not require mitigation. 2.2 miles of this segment cross sedimentary deposits of Quaternary older alluvium. These deposits accumulated during the Pleistocene (~1.8 to 0.01 Ma) and, although not proven to contain fossils, their sedimentary origin indicate a strong but unproven (i.e., undetermined) potential for producing fossil remains. Ground disturbance estimates for these areas of undetermined sensitivity are only levels 1 and 2, indicating low initial impacts and thus, not requiring mitigation.

7.1.6 Segment F

Construction of the new 230 kV transmission line along segments F1 and F2 would traverse 4 miles of sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity and impacts to paleontological resources defined as having only minor sensitivity (see Table 7-1 and Appendix A). These impacts are not significant and would not require mitigation.

7.1.7 Segment G

Construction of the new 230 kV transmission line along Segment G would traverse 11.1 miles of sedimentary deposits defined as having minor, major/undetermined, and maximum sensitivity (see Table 7-1 and Appendix A). In addition 10.1 miles of this segment cross areas underlain by plutonic igneous rocks and metamorphic rocks (including the Pelona Schist) with zero resource sensitivity. 3.7 miles of Segment G traverse sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity; impacts are not significant and would not require mitigation. 4.5 miles of this segment cross sedimentary deposits of Quaternary older alluvium (fluvial and alluvial fan deposits of Pleistocene age; ~1.8 to 0.01 Ma), the Vasquez Formation (alluvial fan, fluvial, and deltaic strata of late Oligocene to early Miocene age; ~26 to 22 Ma), and the San Francisquito Formation (marine sedimentary rocks of late Cretaceous to early Paleocene age ~70 to 60 Ma). Although not proven to contain fossils, the sedimentary origin of Quaternary older alluvium and the Vasquez Formation indicates a strong but unproven (i.e., undetermined) potential for producing fossil remains. The San Francisquito Formation is defined as having major paleontological resource sensitivity. Ground disturbance estimates for these areas of major/undetermined sensitivity are only levels 1 and 2, indicating low initial impacts and thus, not requiring mitigation. 2.3 miles of Segment G traverses sedimentary deposits of the Saugus Formation (fluvial and alluvial fan deposits of late Pliocene to early Pleistocene age; ~3 to 1.5 Ma), the Anaverde Formation (terrestrial and fluvial deposits of late Miocene to early Pliocene age ~6 to 5 Ma), and the Mint Canyon Formation (deltaic, fluvial, and lacustrine deposits of middle to late Miocene age; ~14 to 11 Ma). All of these rock units are known to produce significant paleontological resources and are defined as having maximum sensitivity. Ground disturbance estimates for certain areas of maximum sensitivity are only level 1, indicating low initial impacts and no required mitigation. However, there are also areas of maximum sensitivity where ground disturbance estimates range from level 2 to 4 (i.e., moderate initial impacts) and these impacts would require mitigation. These potential moderate impacts can be reduced to low residual impacts through adoption of appropriate mitigation measures (see Mitigation Measures PR-1 through PR-5).

THIS PAGE INTENTIONALLY LEFT BLANK

7.1.8 Segment 2a

Construction of the new 230 kV transmission line along Segment 2a would traverse 0.4 miles of sedimentary deposits defined as major/undetermined (see Table 7-1 and Appendix A). In addition, 6.1 miles of this segment cross areas underlain by plutonic igneous rocks and metamorphic rocks with zero resource sensitivity. About 0.4 miles of this segment cross sedimentary deposits of Quaternary older alluvium (fluvial and alluvial fan deposits of Pleistocene age; ~1.8 to 0.01 Ma). Although not proven to contain fossils, the sedimentary origin of Quaternary older alluvium indicates a strong but unproven (i.e., undetermined) potential for producing fossil remains. Ground disturbance estimates for certain areas of major/undetermined sensitivity are only level 2, indicating low initial impacts and no required mitigation. However, there are also areas of major/undetermined sensitivity where ground disturbance estimates are level 4 (i.e., moderate initial impacts) and these impacts would require mitigation. These potential moderate impacts can be reduced to low residual impacts through adoption of appropriate mitigation measures (see Mitigation Measures PR-1 through PR-5).

7.1.9 Segment H

Construction of the new 230 kV transmission line along Segment H1 would traverse 2.4 miles of sedimentary deposits defined as having minor and major/undetermined sensitivity (see Table 7-1 and Appendix A). In addition, 0.4 of a mile of this segment crosses areas underlain by plutonic igneous rocks and metamorphic rocks (including the Pelona Schist) with zero resource sensitivity. Two miles of Segment H1 traverse sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity; impacts are not significant and would not require mitigation. About 0.4 of a mile of this segment crosses sedimentary deposits of Quaternary older alluvium (fluvial and alluvial fan deposits of Pleistocene age; ~1.8 to 0.01 Ma). Although not proven to contain fossils, the sedimentary origin of Quaternary older alluvium indicates a strong but unproven (i.e., undetermined) potential for producing fossil remains. Ground disturbance estimates for these areas of major/undetermined sensitivity are only levels 1 and 2, indicating low initial impacts and thus, not requiring mitigation.

Construction of the new 230 kV transmission line along segment H2 would traverse 2.9 miles of sedimentary deposits defined as having minor and maximum sensitivity (see Table 7-1 and Appendix A). In addition, 14.2 miles of this segment cross areas underlain by plutonic igneous rocks and metamorphic rocks (including the Pelona Schist) with zero resource sensitivity. About 0.8 of a mile of Segment H2 traverses sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity; impacts are not significant and would not require mitigation. 2.3 miles of this segment cross sedimentary deposits of the Castaic Formation (marine sandstones of late Miocene to early Pliocene age; ~6 to 5 Ma), the Anaverde Formation (terrestrial and fluvial deposits of late Miocene to early Pliocene age ~6 to 5 Ma), and the Mint Canyon Formation (deltaic, fluvial, and lacustrine deposits of middle to late Miocene age; ~14 to 11 Ma). All of these rock units are known to produce significant paleontological resources and are defined as having maximum sensitivity. Ground disturbance estimates for areas of maximum sensitivity range from level 2 to 6 (i.e., moderate to high initial impacts) and these impacts would require mitigation. These potential moderate impacts can be reduced to low residual impacts through adoption of appropriate mitigation measures (see Mitigation Measures PR-1 through PR-5).

7.1.10 Segment I

Construction of the new 230 kV transmission line along Segment I would traverse 16.3 miles of sedimentary deposits defined as having minor, major/undetermined, and maximum sensitivity (see Table 7-1 and Appendix A). In addition, 18.4 miles of this segment cross areas underlain by plutonic igneous rocks and metamorphic rocks (including the Pelona Schist) with zero resource sensitivity. Nine miles of Segment I traverse sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity; impacts are not significant and would not require mitigation. About 1.3 miles of this segment crosses sedimentary deposits of Quaternary older alluvium (fluvial and alluvial fan deposits of Pleistocene age; ~1.8 to 0.01 Ma). Although not proven to contain fossils, the sedimentary origin of Quaternary older alluvium indicates a strong but unproven (i.e., undetermined) potential for producing fossil remains. Ground disturbance estimates for these areas of major/undetermined sensitivity are only levels 1 and 2, indicating low initial impacts and thus, not requiring mitigation. About six miles of this segment crosses sedimentary deposits of the Castaic Formation (marine sandstones of late Miocene to early Pliocene age; ~6 to 5 Ma), the Anaverde Formation (terrestrial and fluvial deposits of late Miocene to early Pliocene age ~6 to 5 Ma), the Mint Canyon Formation (deltaic, fluvial, and lacustrine deposits of middle to late Miocene age; ~14 to 11 Ma), and the Tick Canyon Formation (fluvial and lacustrine deposits of early Miocene age; ~24 to 16 Ma). All of these rock units are known to produce significant paleontological resources and are defined as having maximum sensitivity. Ground disturbance estimates for areas of maximum sensitivity range from level 2 to 6 (i.e., moderate to high initial impacts) and these impacts would require mitigation. These potential moderate impacts can be reduced to low residual impacts through adoption of appropriate mitigation measures (see Mitigation Measures PR-1 through PR-5).

7.1.11 115th Street

Construction of the new 230 kV transmission line along 115th Street would traverse 4.5 miles of sedimentary deposits defined as having minor and major/undetermined (see Table 7-1 and Appendix A). In addition, 0.3 of a mile of this segment crosses areas underlain by plutonic igneous rocks with zero resource sensitivity. About 3.3 miles of this segment traverse sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity; impacts are not significant and would not require mitigation. About 1.2 miles of this segment cross sedimentary deposits of Quaternary older alluvium (fluvial and alluvial fan deposits of Pleistocene age; ~1.8 to 0.01 Ma). Although not proven to contain fossils, the sedimentary origin of Quaternary older alluvium indicates a strong but unproven (i.e., undetermined) potential for producing fossil remains. Ground disturbance estimates for these areas of major/undetermined sensitivity are only levels 1 and 2, indicating low initial impacts and thus, not requiring mitigation.

7.2 NEW 230 KV CIRCUIT

Construction of the new 230 kV circuit along Segment J would occur in areas underlain by paleontological resources defined as having minor and maximum sensitivity (see Table 7-1). However, because no ground disturbance activities are proposed for this Project element, there would be no significant impacts to paleontological resources and no requirement for mitigation.

7.3 RECONDUCTORING

Reconductoring along Segment K would occur in areas underlain by paleontological resources defined as having minor, major/undetermined, and maximum sensitivity (see Table 7-1 and Appendix A). However, because no ground disturbance activities are proposed for this Project element, there would be no significant impacts to paleontological resources and no requirement for mitigation.

7.4 NEW HASKELL CANYON SWITCHING STATION

Construction of the new Haskell Canyon Switching Station would occur in an area underlain by sedimentary deposits of the Saugus Formation (fluvial and alluvial fan deposits of late Pliocene to early Pleistocene age; ~3 to 1.5 Ma), the Castaic Formation (marine sandstones of late Miocene to early Pliocene age; ~6 to 5 Ma), and the Mint Canyon Formation (deltaic, fluvial, and lacustrine deposits of middle to late Miocene age; ~14 to 11 Ma). These rock units are known to produce significant paleontological resources and are defined as having maximum sensitivity. Ground disturbance estimates for areas of maximum sensitivity range from level 2 to 6 (i.e., moderate to high initial impacts) and these impacts would require mitigation. These potential moderate impacts can be reduced to low residual impacts through adoption of appropriate mitigation measures (see Mitigation Measures PR-1 through PR-5).

7.5 EXPANSION OF BARREN RIDGE SWITCHING STATION

The proposed expansion of the existing Barren Ridge Switching Station would occur in an area underlain by sedimentary deposits of Quaternary alluvium. Because these deposits accumulated relatively recently, they are defined as having only minor sensitivity; impacts are not significant and would not require mitigation.

8.0 ALTERNATIVES

NEPA and CEQA both require consideration of a reasonable range of alternatives to the Proposed Action that would feasibly attain most of the basic objectives of the Project, but avoid or substantially lessen any of the significant or adverse effects of the Project.

8.1 DEVELOPMENT OF ALTERNATIVES

A range of alternatives were identified through a siting analysis, the scoping process, and supplemental studies and consultations. A full discussion of alternatives development can be found in the Alternatives Development Report (POWER 2010).

The regional siting analysis identified nine routing opportunities (Segments A through I) for the new 230 kV transmission line between Barren Ridge Switching Station and the proposed Haskell Canyon Switching Station. Some of the routing opportunities or segments were adjusted or modified based on public input and preliminary environmental review, and preliminary electrical system studies. Each of the segments are discussed in detail, including impact analysis, in Section 7.0 of this report. Several of these segments were not used in the formation of alternatives as discussed below.

Segment E was recommended for elimination from analysis in the EIS/EIR. The Segment would require an additional 6.5 miles of transmission line in comparison to the Proposed Action and would not significantly reduce or avoid impacts to air quality, biological, cultural, visual, and water resources. Segment H was also recommended for elimination, due to increased impacts to air quality and noise, along with safety concerns, related to helicopter construction. Cumulative effects for the Project would also increase because of the further disturbance of revegetated and rehabilitated areas and potential for impacts from three transmission line projects in the same vicinity.

Eight routing opportunities (Segments A, B, C, D, F, G, 2a and I) were combined to create end-to-end routing alternatives for the proposed double-circuit 230 kV transmission line between Barren Ridge Switching Station and the proposed Haskell Canyon Switching Station. In addition to routing segments, each alternative discussed within this section would include other Project components as discussed earlier within this report. These include the addition of a new circuit on existing towers between Castaic Power Plant and Haskell Canyon, reconductoring of the existing BR-RIN transmission line, construction of a new Haskell Canyon Switching Station, and expansion of the existing Barren Ridge Switching Station. Impact assessment and impact results for each of the other Project components listed above, and which are common to each of the alternatives, are described in Section 7.0. Descriptions and impact assessment of the routing alternatives follow in the sections below.

8.2 ALTERNATIVES DESCRIPTION

The following alternatives were identified as a reasonable range of alternatives to the Project that would feasibly attain most of the basic objectives of the Project, but avoid or substantially lessen any of the significant or adverse effects of the Project.

8.2.1 Action Alternatives

In addition to a new double-circuit 230 kV transmission line between the Barren Ridge and Haskell Canyon switching stations, whose route would vary among the action Alternatives, the four action Alternatives would include the following common components: the expansion of the existing Barren Ridge Switching Station, construction of a new Haskell Canyon Switching Station, reconductoring of the existing 230 kV transmission line from the Barren Ridge Switching Station to Rinaldi Substation, and the addition of a new 230 kV circuit on existing towers between the Castaic Power Plant and Haskell Canyon Switching Station. Refer to Figure 8-1.

Alternative 1 (Segments A, C, and D)

The Alternative 1 230 kV double-circuit transmission line comprises the preliminary routing Segments A, C, and D, and is the longest Alternative, at 83 miles long. It would run from the Barren Ridge Switching Station to the unincorporated community of Mojave, while paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines. It would continue south-southwest to parallel the Los Angeles Aqueduct to Lancaster Road, where it would travel west to the I-5 utility corridor. It would then run southeast along LADWP's existing Castaic – Rinaldi corridor to the proposed Haskell Canyon Switching Station.

Helicopter Mitigation

Within the ANF where the terrain is steep and access is limited, the USFS would require that the new double-circuit 230 kV structures be constructed with the use of helicopters (such as the Hughes 500 or Bell 212, or Sikorsky Skycrane). Refer to Figure 8-2, the Identified Helicopter Mitigation Locations Map, which illustrates the identified locations for this mitigation. The use of helicopters for the construction of transmission tower structures would eliminate the need for new access roads to structure locations, and would therefore minimize land disturbance associated with crane pads, structure laydown areas, and the trucks and tractors used for delivery of structures to sites. However, the following site and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas, tower structure vegetation clearing, guard structures at major crossings, wire stringing sites, pullouts, and temporary access roads.

Alternative 2 (Segments A, B, and G) –LADWP's Proposed Action

Alternative 2, LADWP's Proposed Action, comprises Segments A, B, and G and is 61 miles long. It begins at the Barren Ridge Switching Station and runs south, paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines. It travels south from the unincorporated community of Mojave, California through the Antelope Valley and approximately one mile east of the Antelope Valley California Poppy Reserve before continuing onto National Forest System lands and ending at the proposed Haskell Canyon Switching Station. The entire route would remain within designated utility corridors and would parallel existing transmission lines. Refer to Section 1.2, Project Description, for a full description of this Alternative.

Alternative 2a (Segments A, B, G and 2a)

The 230 kV double-circuit transmission line in Alternative 2a comprises the preliminary routing Segments A, B, and G, but includes a re-route (Segment 2a) avoiding the unincorporated community of Green Valley. It is 63 miles long and would be very similar to the Proposed Action (Alternative 2), with 56 miles of the same alignment. Alternative 2a would begin at the Barren Ridge Switching Station and run south, paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines. It would travel south from the unincorporated community of Mojave through the Antelope Valley and approximately one mile east of the Antelope Valley California Poppy Reserve before continuing onto NFS lands and ending at the proposed Haskell Canyon Switching Station. The route would remain within designated utility corridors and would parallel existing transmission lines, with the exception of the nearly seven miles that would be routed around the unincorporated community of Green Valley. Segment 2a would create a new utility corridor through the ANF. The re-route would rejoin Segment G south of the unincorporated community of Green Valley before continuing south and ending at the proposed Haskell Canyon Switching Station.

Three-Circuit Tower Mitigation

In areas where there are ROW expansion constraints and where LADWP has existing 230 kV transmission lines, LADWP is proposing to construct three-circuit towers to carry the existing BR-RIN circuit and two new BR-HC circuits. This would avoid various impacts including the acquisition of residential property in the unincorporated communities of Willow Springs (milepost 27.1 to 27.6) and Elizabeth Lake and Green Valley (milepost 44.6 to 46 and milepost 50.8 to 51.7). This mitigation would be utilized in the same areas that were identified for Three-Circuit Tower Mitigation for the Proposed Project, with the exception of approximately five miles through the unincorporated community of Green Valley, which would not utilize this mitigation. These areas are illustrated in 1-7, the Three-Circuit Tower Mitigation Map.

Helicopter Mitigation

Within the ANF where the terrain is steep and access is limited, the USFS would require that the new double-circuit 230 kV structures be constructed by the use of helicopter. Refer to Figure 8-2, Identified Helicopter Mitigation Locations, which illustrates the identified locations for this mitigation. The use of helicopters for the construction of transmission tower structures would eliminate the need for new access roads to structure locations, and would therefore minimize land disturbance associated with crane pads, structure laydown areas, and the trucks and tractors used for delivery of structures to sites. However, the following site and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas, tower structure vegetation clearing, guard structures at major crossings, wire stringing sites, pullouts, and temporary access roads. The estimated sizes of these auxiliary sites (temporary and permanent) and additional construction information is detailed above in the description of the Proposed Action (Alternative 2) and in Appendix B.

Alternative 3 (Segments A, B, F, and I)

The proposed 230 kV double-circuit transmission line in Alternative 3 comprises preliminary routing Segments A, B, F, and I. It is 76 miles long and would begin at the Barren Ridge Switching Station and run south, paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI lines. It would travel south from the unincorporated community of Mojave through the Antelope Valley and approximately one mile east of the Antelope Valley California Poppy Reserve before continuing southeast past SCE's Antelope Substation. The route would then travel toward the city of Palmdale, parallel to SCE's existing high-voltage transmission lines. It would make a sharp turn to the south to parallel LADWP's existing Victorville – Rinaldi 500 kV and Adelanto – Rinaldi 230 kV transmission lines. This Alternative would then parallel these transmission lines west, crossing two miles of the ANF. The Alternative would then parallel LADWP's 500 kV PDCI line north to the proposed Haskell Canyon Switching Station.

Three-Circuit Tower Mitigation

In areas where there are ROW expansion constraints and where LADWP has existing 230 kV transmission lines, LADWP is proposing to construct three-circuit towers to carry the existing BR-RIN circuit and two new BR-HC circuits. This would avoid various impacts including the acquisition of residential property in the unincorporated communities of Willow Springs (milepost 27.1 to 27.6). Please refer to the small inset map on Figure 1-7.

Avenue L Re-route

To avoid acquisition of private property, a portion of Alternative 3 from mile marker 45.2 to 46.7 was moved to parallel a smaller distribution line south along 90th Street West and then east along West Avenue "L." Refer to Figure 8-3, Avenue L Re-route on Alternative 3.

8.2.2 No Action Alternative

Under the No Action Alternative, the construction of a new 230 kV transmission line, the addition of a new circuit on existing structures from Haskell Canyon to the Castaic Power Plant, the reconductoring of the existing BR-RIN transmission line, the construction of a new Haskell Canyon Switching Station, and the expansion of the existing Barren Ridge Switching Station would not occur. LADWP currently maintains an estimated 147 miles of existing access roads in the Project area, 97 of which are located within the ANF. Current, on-going operation and maintenance activates for existing facilities in the Project area would continue. The EIS/EIR must address the resulting environmental effects from taking no action and compare them to the effects of permitting the Proposed Action or an Alternative to the Proposed Action.

8.3 IMPACT RESULTS—ROUTING ALTERNATIVES

8.3.1 Alternative 1 (Segments A, C, and D)

Alternative 1, which includes segments A, C, and D, has the potential to create significant impacts to paleontological resources with maximum sensitivity occurring along a 25-mile section of the southern portion of Segment D between MP 22.4 and the proposed Haskell Canyon Switching Station. A total of 8 miles of this segment are slated for helicopter construction of lattice towers and all this mileage is underlain by rock units having maximum sensitivity (7.7 miles of Ridge Route Formation and 0.7 miles of Peace Valley Formation). Because of steep terrain in these areas, ground disturbance would likely create initial impacts to paleontological resources that would also require mitigation. As summarized in Table 7-1, these significant impacts include a total of 13.1 miles of moderate initial impacts and 1.2 miles of high initial impacts. In addition, construction of the proposed Haskell Canyon Switching Station has the potential to create significant impacts to paleontological resources with maximum sensitivity occurring within the footprint of the new switching station. In contrast, expansion of the existing Barren Ridge Switching Station would not create any significant impacts to paleontological resources, nor would reconductoring of the existing Barren Ridge-Rinaldi transmission line or the stringing of new lines between Haskell Canyon Switching Station and the Castaic Power Plant. Construction of Alternative 1 would avoid potential significant impacts to paleontological resources occurring along segments G and I. Portions of these two segments are underlain by geologic rock units known to contain fossil remains of Miocene land mammals.

8.3.2 Alternative 2 (Segments A, B, and G)—LADWP's Proposed Action

Alternative 2, which includes segments A, B, and C, has the potential to create significant impacts to paleontological resources with maximum sensitivity occurring along a short, 2-mile section of the southern portion of Segment G between MP 19.2 and 21.2. As summarized in Table 7-1, these significant impacts include a total of 2.2 miles of moderate initial impacts. In addition, construction of the proposed Haskell Canyon Switching Station has the potential to create significant impacts to paleontological resources with maximum sensitivity occurring within the footprint of the new switching station. In contrast, expansion of the existing Barren Ridge Switching Station would not create any significant impacts to paleontological resources, nor would reconductoring of the existing Barren Ridge-Rinaldi transmission line or the stringing of new lines between Haskell Canyon Switching Station and the Castaic Power Plant. Construction of Alternative 2 would avoid potential significant impacts to paleontological resources occurring along segments D and I. Portions of these two segments are underlain by geologic rock units known to contain fossil remains of Miocene land mammals.

8.3.3 Alternative 2a (Segments A, B, G, and 2a)

Alternative 2a, which bypasses the unincorporated community of Green Valley, has the potential to create significant impacts to paleontological resources with major/undetermined sensitivity occurring along a short, 0.3-mile section between MP 6.0 and 6.3. A total of 4 miles of this segment are slated for helicopter construction of lattice towers and all this mileage is underlain by rock units having zero resource sensitivity. As summarized in Table 7-1, these significant impacts include a total of 0.3 miles of moderate initial impacts. Construction of Alternative 2a would avoid potential significant impacts to paleontological resources occurring along segments D and I. Portions of these two segments are underlain by geologic rock units known to contain fossil remains of Miocene land mammals.

8.3.4 Alternative 3 (Segments A, B, F, and I)

Alternative 3, which includes segments A, B, F, and I, has the potential to create significant impacts to paleontological resources with maximum sensitivity occurring along short, 3.4-mile and 2.7-mile sections of the southern portion of Segment I between MP 24.4 and 27.8 and MP 29.2 and 31.9, respectively. As summarized in Table 7-1, these significant impacts include a total of 5.2 miles of moderate initial impacts and 0.2 of a mile of high initial impacts. In addition, construction of the proposed Haskell Canyon Switching Station has the potential to create significant impacts to paleontological resources with maximum sensitivity occurring within the footprint of the new switching station. In contrast, expansion of the existing Barren Ridge Switching Station would not create any significant impacts to paleontological resources, nor would reconductoring of the existing Barren Ridge-Rinaldi transmission line or the stringing of new lines between Haskell Canyon Switching Station and the Castaic Power Plant. Construction of Alternative 3 would avoid potential significant impacts to paleontological resources occurring along segments D and G. Portions of these two segments are underlain by geologic rock units known to contain fossil remains of Miocene land mammals.

8.4 NO ACTION ALTERNATIVE

The No Action Alternative would avoid potential impacts to paleontological resources by eliminating all proposed construction activities along individual Project segments.

8.5 CUMULATIVE EFFECTS

Cumulative effects to paleontological resources are those effects that result from impacts of the BRRTP when incrementally added to impacts of other past, present, and/or future projects. Analysis of cumulative effects places project-specific impacts into a broader context that takes into account the full range of impacts to paleontological resources by projects taking place over a given space and time.

8.5.1 Cumulative Projects List – Major Present and Reasonably Foreseeable Future Actions

The cumulative projects list is used to provide a general context for the cumulative effects. This list includes present and reasonably foreseeable future actions in the Project vicinity that have the potential to combine with the Proposed Action or Alternatives. While a distinct impact area for cumulative impacts and specific present and reasonably foreseeable actions is determined individually for each resource area, collectively, the projects listed below represent the major known and anticipated activities that may occur in the general Project area. The Cumulative Projects Map (Figure 8-4) illustrates the location of energy infrastructure and other major projects in reference to the Proposed Action and Alternatives.

As the project list comprises projects in various stages of planning and development, it is likely that some of these projects would be completed as currently proposed while others would not. To be conservative, the cumulative analysis assumes that all projects listed would be built and in operation during the operating lifetime of the proposed Project. The list was developed in consultation with the following agencies:

- USFS – Angeles National Forest (ANF)
- BLM – Ridgecrest Field Office

- BLM – Palm Springs Field Office
- United States Air Force – Edwards Air Force Base
- Kern County – Planning Department
- Los Angeles County – Department of Regional Planning
- City of California City
- City of Lancaster
- City of Palmdale
- City of Santa Clarita
- City of Los Angeles
- City of San Fernando
- LADWP

THIS PAGE INTENTIONALLY LEFT BLANK

Energy Infrastructure Projects

Transmission Projects

Antelope Transmission Project – Construction of Southern California Edison's (SCE) proposed Antelope Transmission Project is underway and is proceeding in three sequential segments. Construction of Segments 1, 2 and 3A have been completed. Construction of Segment 3B, from Windhub Substation to and including Highwind Substation, has not started and no schedule has been developed by SCE (California Public Utilities – Current Projects).

Segment 1, Antelope – Pardee 500 kV Transmission Line, involved the construction of a new 25.6-mile transmission line between SCE's existing Antelope Substation in the city of Lancaster and SCE's existing Pardee Substation in Santa Clarita, with modifications to and/or expansion of the substations. The line was constructed in an existing SCE 66 kV transmission line right-of-way (ROW) for 23 miles, and within a new ROW for 18 miles. The line is initially energized to 220 kV to serve existing energy demand and can be upgraded to 500 kV to accommodate future needs.

Segment 2, Antelope – Vincent 500 kV Transmission Line, consists of a new 17.8 mile transmission line between the Antelope Substation and SCE's existing Vincent Substation near Acton. Similar to Segment 1, the line would initially be energized at 220 kV and upgraded to meet future needs.

Segment 3, Antelope – Tehachapi Transmission Line, consists of two phases. The first phase, 3A, would involve the construction of a new 26.1-mile 500 kV transmission line between the Antelope Substation and a proposed new substation in the vicinity of the unincorporated community of Mojave (Substation 1). Similar to Segments 1 and 2, this line would be initially energized at 220 kV and upgraded to meet future needs. The second phase, 3B, would involve the construction of a new 9.4-mile 220 kV transmission line from the proposed Substation 1 to a proposed new substation in the Monolith area (Substation 2).

Tehachapi Renewable Transmission Project (TRTP) – SCE is proposing to construct the TRTP, which would involve new and upgraded transmission infrastructure along 173 miles of new and existing rights-of-way, in southern Kern County, portions of Los Angeles County including the ANF, and the southwestern portion of San Bernardino County. Stated objectives for the project include providing the electrical facilities necessary to integrate levels of wind generation in excess of 700 MW and up to 4,500 MW in the Tehachapi Wind Resource Area (California Public Utilities – Current Projects).

The environmental review process for the project is currently underway. Construction began in April 2010 on approved sections. Project construction is estimated to be completed in 2015.

The project is composed of Segments 4 through 11, with Segments 4 through 8 and Segments 10 and 11 being transmission facilities, and Segment 9 being the addition and upgrade of substation facilities. Proposed transmission lines would be constructed primarily within existing rights-of-way. Major project components include:

- Constructing two new single-circuit 220 kV transmission lines within 4 miles of new ROW between the Cottonwood Substation and proposed Whirlwind Substation (Segment 4);
- Constructing a new single-circuit 500 kV transmission line within 16 miles of new ROW between the Antelope Substation and proposed Whirlwind Substation (Segment 4);
- Rebuilding 18 miles of the existing Antelope – Vincent and Antelope – Mesa 220 kV transmission lines to 500 kV standards within existing ROW between the Antelope and Vincent Substations (Segment 5);

- Rebuilding 27 miles of the existing Antelope – Mesa 220 kV transmission line and 5 miles of the existing Rio Hondo – Vincent 220 kV transmission line to 500 kV standards between the Vincent Substation and the southern boundary of the ANF (Segment 6);
- Rebuilding 16 miles of the existing Antelope – Mesa 220 kV transmission line to 500 kV standards between the southern boundary of the ANF and Mesa Substation (Segment 7);
- Rebuilding 33 miles of the existing Chino – Mesa 200 kV transmission line to 500 kV standards between a point 2 miles east of the Mesa Substation and the Mira Loma Substation (Segment 8);
- Rebuilding 7 miles of the existing Chino – Mira Loma No. 1 220 kV transmission line from single-circuit to double-circuit structures (Segment 8);
- Constructing a new 500/220 kV Whirlwind Substation 4 to 5 miles south of the Cottonwood Substation (Segment 9);
- Upgrading the existing Antelope, Vincent, Mesa, Gould, and Mira Loma Substations to accommodate new transmission line construction and system compensation elements (Segment 9);
- Constructing a new single-circuit 500 kV transmission line within 17 miles of new ROW between the Windhub Substation and proposed Whirlwind Substation (Segment 10);
- Rebuilding 19 miles of existing 220 kV transmission line to 500 kV standards in existing ROW between the Vincent and Gould Substations (Segment 11);
- Adding a new 220 kV circuit between the Mesa and Gould Substations on the vacant side of the existing Eagle Rock – Mesa 220 kV transmission line double circuit structures (Segment 11); and
- Installing associated telecommunications infrastructure.

Generation Projects

Numerous wind and solar generation projects are in various stages of planning and development within the Project vicinity. Projects considered include the projects currently undergoing environmental review or projects that have been recently approved. Table 8-1 below summarizes the major known projects and their current status as of April 2011 (County of Kern Environmental Documents and AV Solar Ranch One).

TABLE 8-1. PROPOSED GENERATION PROJECTS IN THE PROJECT VICINITY

Project Name	Project Type	Approximate Generation	Area (acres)	Location	Status
Alta East Wind Project	Wind	300 MW	3,660	Kern County	Application to Kern County deemed complete on Aug. 2010
Alta Wind Energy Center: Alta-Oak Creek Mojave Project	Wind Turbine	800 MW	9,175	Kern County	Approved by Kern County Dec. 2009
Antelope Valley Solar Project	Solar Photovoltaic	650 MW	5,698	Kern County	Draft EIR released April 2011
AV Solar Ranch One	Solar Photovoltaic	230 MW	21,000	Los Angeles County	Final EIR completed Aug. 2010
Avalon Wind Project	Wind	255 MW	10,000	Kern County	Application to Kern County deemed complete on July 2010
Beacon Solar Energy Project	Concentrated Solar	250 MW	2,012	Kern County	Application for Certification approved Aug. 2010
Catalina Renewable Energy Project	Wind Turbine & Solar Photovoltaic	350 MW	7,472	Kern County	Notice of Preparation for a Draft EIR filed Feb. 2011

Project Name	Project Type	Approximate Generation	Area (acres)	Location	Status
Clearvista Wind Project	Wind Turbine	40 MW	226	Kern County	Draft EIR released Nov. 2010
Edwards Air Force Base Solar Project	Solar	500 MW	3,288	Kern County	Lease execution anticipated 2012
Lower West Wind Energy Project	Wind Turbine	14 MW	185	Kern County	Draft EIR released April 2011
Monte Vista Solar Array	Solar Photovoltaic	126 MW	1,040	Kern County	Notice of Preparation for a Draft EIR filed March 2010
Morgan Hills Wind Project	Wind	230 MW	3,604	Kern County	Application submitted Nov. 2010
North Sky River Wind Project	Wind Turbine	326 MW	1,330	Kern County	Notice of Preparation for a Draft EIR filed Nov. 2010
Pacific Wind Energy Project	Wind Turbine	151 MW	8,300	Kern County	Approved by Kern County Oct. 2010
Pahnamid Wind Energy Project	Wind Turbine	411 MW	7,106	Kern County	Notice of Preparation for a Draft EIR filed April 2011
PdV Wind Energy Project	Wind Turbine	300 MW	5,820	Kern County	Approved by Kern County July 2008
Pine Canyon Wind Project	Wind Turbine	150 MW	12,000	Kern County	Preliminary planning
Pine Tree Solar Project	Solar Photovoltaic	10 MW	75	Kern County	Preliminary planning
Pine Tree Wind & Expansion	Wind Turbine	135 MW	n/a	Kern County	Preliminary planning
RE Distributed Solar Project	Solar Photovoltaic	221 MW	1,709	Kern County	Notice of Preparation for a Draft EIR filed Jan. 2011
Ridge Rider Solar Park Project	Solar Photovoltaic	38 MW	475	Kern County	Notice of Preparation of a Draft EIR filed March 2010
Rising Tree Wind Farm	Wind Turbine	234 MW	2,745	Kern County	Notice of Intent to prepare a EIS/EIR filed Jan. 2011
Rosamond Solar Array	Solar Photovoltaic	155 MW	1,177	Kern County	Notice of Preparation of a Draft EIR filed March 2010
Rosamond Solar Project	Solar Photovoltaic	120 MW	960	Kern County	Approved by Kern County Nov. 2010
Sand Canyon Wind Projects	Wind Turbine	40 MW	300	Kern County	Notice of Preparation of a Draft EIR filed Oct. 2010
Willow Springs Solar Array Project	Solar Photovoltaic	160 MW	1,402	Kern County	Notice of Preparation of a Draft EIR filed March 2010
Windstar Wind Energy Project	Wind Turbine	65 MW	1,007	Kern County	Approved by Kern County April 2009

There are also plans in various stages of development to establish additional wind and solar energy projects on BLM land in the Project vicinity. The submission of an application to BLM is a preliminary step in the project planning process, but not all applications ultimately result in successful project development. Below is a list of current applications for wind and solar energy generation projects in the Project vicinity submitted to BLM's Ridgecrest Field Office as of February 2010 (U.S. Department of the Interior, Bureau of Land Management – Renewable Energy).

TABLE 8-2. BLM RIDGECREST OFFICE APPLICATIONS FOR WIND AND SOLAR ENERGY GENERATION PROJECTS IN THE PROJECT VICINITY.

Serial Number	Applicant	Date Application Received, ROW Grant Issued, Last Amended Date	Approximate Area (Acres)	Project Type	Location

CACA 51561	Power Partners Southwest	12/11/09	1,160	Pending Wind	Kern County

Other Major Projects

Transportation and Public Facilities

California High Speed Rail – This project proposes a ±700-mile high speed rail line from Sacramento to San Diego. The Statewide Programmatic EIS/EIR was completed in 2005, and the Bay Area to Central Valley High-Speed Train Program EIS/EIR was completed in 2008. Multiple second-tier project-level environmental documents (with preliminary engineering design) are currently underway (California High Speed Rail Authority).

Pacific Pipeline Storm Relocation Project and Access Road Repairs – Pacific Pipeline is proposing to relocate several miles of crude oil pipeline to more stable ground within the ANF. Project implementation was expected in November 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Antelope Valley Water Bank Project – This project proposes to develop facilities to store and recharge imported surface water and associated delivery and distribution pipelines. The 13,440-acre facility area would be bounded by the Kern/Los Angeles County border line (also known as Avenue A) to the south and Rosamond Boulevard to the north, and between 170th Street West and 100th Street West in unincorporated Kern County (U.S. Department of the Interior, Bureau of Reclamation – Mid-Pacific Region).

Soledad Canyon Cemex Project – The Soledad Canyon Cemex project would be a 56-million-ton sand and gravel mining project in the Soledad Canyon area. The BLM approved the project with mitigating measures in 2000, and the Interior Board of Land Appeals affirmed that decision in 2002. A City of Santa Clarita challenge to the US Supreme Court was denied in 2006. This project is pending development with ongoing challenges and delays (Cemex United States).

Community Development

Centennial, California – The proposed project site consists of 12,000 acres located one mile east of Interstate 5 (I-5) and adjacent to State Highway 138 in Los Angeles County. The project would include a specific plan and subdivision entitlements (i.e., tract maps and conditional use permits) for a master planned community. The specific plan proposes a maximum of 23,000 dwelling units and 14 million total square feet of non-residential development of employment areas (12,233,390 square feet) and retail serving centers (1,986,336 square feet), anticipated to be built over approximately 20 years, with build-out expected in 2030. If the project is approved by Los Angeles County, it is estimated that the non-residential development may generate approximately 31,000 jobs. The draft Specific Plan for the unincorporated community of Centennial was submitted to Los Angeles County in February 2003 and is currently being reviewed by the county (Centennial, California).

Maintenance and Landscape Management Projects

Bouquet Canyon Road Realignment – Los Angeles County Department of Public Works is proposing to straighten some sections of Bouquet Canyon Road and to raise the road surface by approximately nine feet. A Memorandum of Understanding between ANF and Los Angeles County is currently under development to initiate the project (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

San Francisquito Road Rehabilitation and Sediment Disposal Site – Los Angeles County Department of Public Works is proposing a road realignment and new bridge along San Francisquito Road within the ANF and to use eight acres of Forest land as a spoils site in support of construction activities. Public Scoping began in June 2007, and a decision was expected in September 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Old Ridge Route Storm Damage Repair – USFS is proposing to repair and provide maintenance to seven storm-damaged locations along the Old Ridge Route in ANF. A decision on the project is expected in late 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Livestock Grazing Allotments – BLM currently authorizes both cattle and sheep grazing on 11 grazing allotments in and around the project area. The livestock are authorized with 10 year permits/leases and yearly authorizations. These allotments encompass over one half million acres of BLM-managed lands. The number of livestock grazed each year depends upon weather conditions. The majority of the livestock are sheep. The number of sheep average around thirty thousand head. Three of the allotments support several thousand head of cattle (Harris 2010).

Tule Ridge/South Portal Fuels Reduction Project – USFS proposes fuels reduction and re-establishment of a fuel break to provide protection to unincorporated community of Green Valley. The project would also enhance wildlife for mammals and birds (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Jupiter Fuelbreak Project – USFS proposes to re-establish an existing fuel break that begins southwest of the unincorporated community of Green Valley and travels east, bisecting Jupiter Mountain, before heading south to Bouquet Reservoir.

Santa Clara/Mojave River Rangers District Plantation Maintenance Project – The proposed project would consist of vegetation maintenance at 13 plantations located within the ANF in order to reduce wildfire risk, and improve wildlife habitat and the vitality of individual remaining trees. Proposed actions include removal of dead trees, thinning of live trees, pruning, removing weeds, and planting for reforestation where necessary. This action was approved by the District Ranger in January 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Lake Hughes Plantation Restoration Project – The proposed project would restore unauthorized off-highway vehicle trails at the Christian and Taylor Plantations located within the ANF in order to reduce soil erosion, the spread of weeds, destruction of native plants, soil compaction, and wildlife habitat loss. Proposed actions include recontouring and decompacting soils, reseeding with native species, and reinforcing check dams. The project was approved by the District Ranger in 2009 and scheduled for implementation in January 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Bouquet and San Francisquito Habitat Improvement Project – The project proposes invasive species removal in Bouquet and San Francisquito Canyons (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Local Projects

In conjunction with the major projects listed above, a summary of local foreseeable projects within the study area that could contribute to cumulative effects are summarized in the table below. These proposed projects were gathered from applications to the planning departments of the various jurisdictions and have been categorized by project type.

TABLE 8-3. PROPOSED LOCAL PROJECTS IN THE PROJECT VICINITY.

	Kern County	Los Angeles County[1]	City of California City	City of Palmdale[2]	City of Lancaster	City of Santa Clarita	City of Los Angeles	City of San Fernando
Single Family Residential (may include multiple units)	1	96	0	14	93	10	2	2
Multi Family Residential (may include multiple units)	28	9	0	9	2	1	2	1
Schools	2	2	0	9	2	0	0	0
Religious Uses	10	7	0	13	0	0	1	1
Recreational Facilities	7	5	0	7	1	0	0	1
Public Facilities – police, fire, library, correctional	2	5	0	4	0	0	0	0
Commercial/ Office Development	40	33	0	96	6	21	2	7
Hotels/Motels	1	0	0	9	2	1	1	2
Medical/Care Facilities	4	6	0	16	0	1	0	1
Industrial Facilities	20	0	0	17	1	6	2	2
Mining Operations	15	0	0	4	0	0	0	0
RV Facilities	2	0	0	0	0	0	0	0
Animal Facilities	8	6	0	1	0	0	0	0
Aviation Facilities	2	0	0	0	0	0	0	0
Non-Commercial Energy Facilities	1	2	0	0	0	0	0	0

[1] Projects listed for Los Angeles County include all projects that could contribute to cumulative effects within the following County Districts: Antelope Valley West, Bouquet Canyon, Castaic Canyon, Chatsworth, Lancaster, Leona Valley, Mount Gleason, Newhall, North Palmdale, Palmdale, Quartz Hill, Sand Canyon, Soledad. Some identified projects included may be outside of the study area.

[2] Projects listed for the City of Palmdale include all projects that could contribute to cumulative effects within the City. Some identified projects included may be outside of the study area.

8.5.2 Cumulative Impacts

Overall, foreseeable projects on federal, State, county, city, and private land would probably encompass over 89,000 acres of development, although the extent of ground disturbance within each project footprint would vary widely, as would the potential for adverse effects to paleontological resources. Table 8-4 briefly summarizes the ranges of factors within different types of projects that could affect paleontological resources.

TABLE 8-4. POTENTIAL SOURCES OF IMPACTS TO PALEONTOLOGICAL RESOURCES CAUSED BY DIFFERENT TYPES OF PROJECTS

Project Type	Potential Ground Disturbance Impacts
Transmission Projects	Access roads, vegetation clearance, structure placement
Generation Projects (Wind and Solar)	Access roads, vegetation clearance, turbine tower/panel foundations
Transportation and Public Facilities	Installation of pipeline, excavation for water bank
Recreation and Community Development	Excavation, clearing and grading
Local Projects	Excavation, construction of access roads, grading, clearing etc.

A cursory review of the major pending projects reveals that few directly overlap with the various proposed BRRTP Alternatives. Further, when considering only those portions of the BRRTP Alternatives where moderate and/or high initial impacts to paleontological resources of major or maximum sensitivity are likely, it appears that only Alternative 1 has the potential for significant cumulative effects. In addition, although the potential to encounter paleontological resources along portions of all three Project Alternatives is considered high, standard conditions for monitoring and fossil recovery pertaining to paleontological resources that may be unearthed during construction of any ongoing or future projects in the area would minimize potential cumulative impacts to a level that is considered less than significant.

APPENDIX B: DETAILED CONSTRUCTION, OPERATION AND MAINTENANCE PROCESS

THIS PAGE INTENTIONALLY LEFT BLANK

BARREN RIDGE RENEWABLE TRANSMISSION PROJECT

Detailed Construction, Operations and Maintenance Process

POWER ENGINEERS

BRRTP CONSTRUCTION, OPERATION AND MAINTENANCE

1.0 230 KV DOUBLE-CIRCUIT TRANSMISSION LINE

1.1 CONSTRUCTION SEQUENCE

Construction of a transmission line involves the following general sequence of events: surveying the centerline; identifying and constructing access roads; clearing right-of-way and tower sites (including construction yards and batch plants); installing foundations; assembling and erecting the towers; clearing, pulling, tensioning, and splicing sites; installing ground wires and conductors; installing counterpoise; switching station tie in; and cleanup and site reclamation. Various phases of construction would occur at different locations throughout the construction process for the Barren Ridge Renewable Transmission Project (BRRTP). This would require several contractors operating at the same time and in different locations.

The following section describes the construction components necessary for the assembly and installation of the proposed double-circuit transmission line. The description of transmission line construction sequencing and estimates for construction sites would also be relevant for the additional transmission line construction activities associated with the installation of the Castaic-Haskell Canyon #4 circuit on existing structures, and the reconductoring of the Barren Ridge – Rinaldi (BR-RIN) transmission line between the Barren Ridge Switching Station and the Rinaldi Substation.

1.1.1 Surveying Activities

The Los Angeles Department of Water and Power (LADWP) must first obtain survey permits for the portion of the Project crossing federal lands managed by the U.S. Department of Agriculture, Forest Service (USFS) and the U.S. Department of the Interior, Bureau of Land Management (BLM), and rights-of-entry for private lands. This would include the issuance of a 50-year term Special Use Permit to LADWP by the USFS and a 30-year term (renewable) Right-of-Way Grant issued by the BLM. For survey on affected private lands, LADWP would need to negotiate rights-of-entry with the local landowners. Once survey permits are obtained, construction survey work would consist of locating the centerline, tower center hubs, ROW boundaries, and tower access roads, some of which would be located outside of the ROW boundaries. Whenever possible, location of the ROW and Project facilities would be laid out to avoid identified sensitive resources. All of these activities would begin approximately one year prior to the start of construction. Cultural resources and necessary additional threatened and endangered species intensive surveys would be conducted once the survey of the centerline and access roads is completed and clearly marked.

Necessary pre-construction geotechnical investigations would include geological field mapping of each tower site, and borings by drill rig for soil sampling and bedrock corings to determine soil densities and bedrock strength. Test locations would include angle points between the Barren Ridge Switching Station and the Angeles National Forest (ANF), and five to ten locations along the selected alignment within the ANF. Seismic analysis of tower sites for slope stability would also be necessary in mountainous areas of the ANF. Existing roads would be used as much as possible, but some new roads could be required.

1.1.2 Preconstruction Weed Removal

LADWP/ANF/BLM shall prepare and implement a comprehensive, adaptive Weed Control Plan on NFS/BLM lands for pre-construction and construction invasive weed abatement. A pre-construction weed inventory shall be conducted by surveying all areas subject to ground-disturbing activity, including, but not limited to, tower pad preparation and construction areas, tower removal sites, pulling and tensioning

sites, assembly yards, and areas subject to grading for new or improved access and spur roads. In areas subject to ground disturbance, weed infestations shall be treated prior to construction according to control methods and practices for invasive weed populations designed in consultation with the USFS/BLM. The Weed Control Plan shall be updated and utilized for eradication and monitoring post construction. Weed control treatments shall include all legally permitted herbicide, manual, and mechanical methods applied with the authorization of the USFS/BLM. The application of herbicides shall be in compliance with all state and federal laws and regulations under the prescription of a Pest Control Advisor (PCA), where concurrence has been provided by the USFS/BLM, and implemented by a Licensed Qualified Applicator. Herbicides shall not be applied during or within 24 hours of a scheduled rain event. Herbicides shall not be used within Riparian Conservation Areas (RCAs) on the ANF without approval of the USFS. In riparian areas, only water-safe herbicides shall be used. Herbicides shall not be applied when wind velocities exceed six miles per hour. Where manual and/or mechanical methods are used, disposal of the plant debris will follow the regulations set by the USFS/BLM. The timing of the weed control treatment shall be determined for each plant species in consultation with the USFS/BLM (on NFS/BLM lands, respectively) with the goal of controlling populations before they start producing seeds.

1.1.3 Construction of Access Roads

The construction, operation, and maintenance of the proposed transmission line would require that heavy vehicles access tower sites along the right-of-way. Where new access roads are required, they would be constructed to support the weight of these vehicles and would typically be 16 feet wide, consisting of a 14-foot driving surface with a side drainage system between one and two feet in width. Permanent roads would be constructed where necessary for operation or maintenance, or where it is required by the landowner or land managing agency. Road standards would be addressed specifically in the Construction, Operation, and Maintenance Plan (COM Plan) and the Plan of Development (POD) during the engineering phase of the Project, and prior to a Notice to Proceed from the USFS and BLM.

Dependent upon final design and mitigation, some temporary access roads may be constructed as part of the Project. These would typically be 16 foot wide roads, but would typically have no improved ditch drainage systems. Most temporary roads would be constructed by crushing vegetation. In some areas, material and topsoil from the temporary roads would be bladed to one or both sides to facilitate rehabilitation. Following construction, bladed material can be re-spread across the disturbed road section. Seeds and roots contained within the re-spread topsoil layer normally provide a natural source for new growth.

Existing paved and unpaved highways and roads would be used where possible. Roads along existing utility corridors would also be used where possible to minimize new access road construction. In locations where existing roads can be used that are located in close proximity to the proposed centerline of the transmission line, only spur roads to the tower sites would be required. New access roads and spur roads would likely be constructed into the right-of-way where existing roads do not exist. Table 1 lists the estimated ground disturbance of access and spur roads based on terrain.

TABLE 1. ACCESS AND SPUR ROAD GROUND DISTURBANCE ESTIMATES

Ground Disturbance Categories	Access Roads		Spur Roads (average width 16 feet)	
	Average Miles of Roads Per Mile of Transmission Line	Average Acres of Disturbance Per Mile of Transmission Line*	Average Miles of Roads Per Mile of Transmission Line	Average Acres of Disturbance Per Mile of Transmission Line
1. Existing roads or agricultural land; no widening anticipated	n/a	n/a	0.3	0.6
2. Existing 8 ft wide roads that require an additional 8 ft of widening	1.0 to 2.5	Permanent 0.9 to 2.4	0.3	0.6
3. Construct new road on flat terrain (0-10%)	1.0 to 2.5	Permanent 1.9 to 4.8	0.3	0.6
4. Construct new road on sloping terrain (10-20%)[1]	2.5 to 4.0	Temporary 7.3 to 11.6 Permanent 4.8 to 7.7	0.5	1.0
5. Construct new road on steep terrain (20-30%)[1, 2]	4.0 to 6.0	Temporary 23.3 to 34.9 Permanent 7.7 to 11.6	0.8	1.6
6. Construct road on very steep terrain (greater than 30%)[1, 2]	6.0 to 8.0	Temporary 69.8 to 93.1 Permanent 11.6 to 15.5	1.0	1.9

[1] After construction of the transmission line, all access roads in Categories 4 through 6 would be restored back to 16 feet wide.
[2] On steep terrain (approximately 25% or higher) with limited access on the Angeles National Forest, the USFS may require Helicopter Mitigation.

Wherever possible, roads would be built at right angles to streams and washes. Culverts or other drainage structures would be installed as necessary across drainages, but the roads would usually follow the natural grade. In addition, road construction would include dust-control and erosion control measures in sensitive areas. All existing roads would be left in a condition equal to or better than their condition prior to the construction of the transmission line without changing their service level. Gates would be installed where required at fenced property lines to restrict general vehicular access from or to the right-of-way. Where identified within the environmental studies for mitigation purposes, access roads may be excluded or limited within specific sensitive areas, such as Riparian Conservation Areas (RCAs) on the Angeles National Forest.

1.1.4 Clearing Right-of-Way

The clearing of some natural vegetation may be required. However, selective clearing would be performed only when necessary to provide for surveying, electrical safety clearances, line reliability, and maintenance. Trimming or removal of mature vegetation, under or near the conductors, would be done to provide adequate electrical clearance as required by the National Electrical Safety Code, the North American Electrical Reliability Corporation, and California Public Utilities Commission General Order 95 standards.

Trees that could fall onto the lines or affect lines during wind-induced line swing would be removed. Normal clearing procedures are to top or remove large trees and not disturb smaller trees. Where there is a direct conflict between trees and clearance standards, the removal of trees would be jointly reviewed and agreed upon between LADWP and the owners or managers of the property. Rights-of-way would not be chemically treated unless necessary to comply with requirements of a permitting agency. On National Forest System (NFS) lands, approved herbicides would be utilized within the Project area on select invasive plant species. Invasive plant surveys and control would continue for the life of the Project.

1.1.5 Tower Site Clearing

After access roads are developed, preparation of individual structure sites would be required to install the structures. At tower locations, work areas of up to 200 feet squared in flat terrain and up to 200 by 250 feet in areas with slopes greater than eight percent may be needed. Within the work areas, at some tower locations, a level cleared area (pad) may be necessary to complete the construction of the towers. However, many tower sites would be considerably smaller depending on the size of the tower, the terrain, resource considerations, and whether helicopter construction was used, among other factors. The work area would be required for the location of tower footings, assembly of the tower, and the necessary crane maneuvers. Vegetation would be mostly crushed, and cleared only when necessary. All pads not needed for normal transmission line maintenance would be graded to blend as near as possible with the natural contours, and revegetated where required by a permitting agency. See Table 2 for tower specifications and Table 5 for estimated temporary and permanent ground disturbance associated with the double-circuit steel lattice towers.

TABLE 2. DOUBLE-CIRCUIT STEEL LATTICE TOWER SPECIFICATIONS

Tower Placement Details	Specifications	
	Categories 1 through 3 Flat (0 – 10% slope)	Categories 4 through 6 Mountainous (10 – 30% slope)
Towers per mile	±5	±5
Average span length	1,100 ft.	1,000 ft.
Average height Ground to lowest attachment	115 ft.	105 ft.
Upper body height	52 ft.	52 ft.
Overall tower height	167 ft.	157 ft.
Typical range of heights of new towers	120 – 195 ft.	110 – 185 ft.

1.1.6 Staging Areas and Batch Plants

It is anticipated that one or two construction yards or staging areas would be required for materials storage, construction equipment, construction vehicles, and temporary construction offices. Staging areas would be approximately five acres in size, and located centrally or near each end of the transmission line route. The staging areas would be located on previously disturbed private land and would be level and surfaced with crushed aggregate base. The LADWP would negotiate with landowners for specific locations of the staging areas.

Concrete for use in constructing foundations would be dispensed from a portable concrete batch plant located at approximately 15 mile intervals. A rubber-tired flatbed truck and tractor would be used to relocate each plant along the right-of-way. Commercial ready-mix concrete would be used when access to tower construction sites is economically feasible.

The construction yards and batch plants would be located on private land and serve as field offices, reporting locations for workers, parking space for vehicles and equipment, sites for material storage, and stations for equipment maintenance. Facilities would be fenced and their gates locked. Security guards would be stationed where needed. See Table 3 for estimated ground disturbance associated with the staging sites and batch plants.

TABLE 3. STAGING SITES AND BATCH PLANT GROUND DISTURBANCE ESTIMATES

Disturbance Description	**Categories 1 through 3 Flat (0 – 10% slope)***	
	Maximum Estimated Disturbance Dimension per site	**Average Disturbance**
Material staging sites (2 sites)	400 x 540 ft. (5 acres)	N/A
Concrete batch plants (3 sites maximum)	2 acres, 30 mile haul distance	0.2 acre per mile
Total Average Disturbance	**0.2 acre per mile**	

*Material staging sites and concrete batch plants would not be built on terrain above 10% slope.

1.1.7 Foundation Installation

Tower foundations for the lattice structures would consist of drilled concrete piers. The foundation process would start with the boring of four holes for each lattice structure or one hole for each TSP. The holes would be bored using truck- or track-mounted excavators with various diameter augers to match diameter and depth requirements of the foundation sizes.

For a typical suspension lattice tower, each hole would typically be four feet in diameter and 25 feet deep, depending on soil conditions. For the larger angle or dead-end structures, foundations could be up to 30 or more feet deep, depending on soil conditions. Each foundation would extend above the ground line between six inches and four feet. In extremely sandy areas, soil stabilization by water or a gelling agent may be used prior to excavation. Refer to Figure 1 and Figure 2 for typical foundation details for double-circuit towers.

Following excavation of the foundation holes, each footing would be constructed by placing formwork, reinforcing steel and a tower stub into the foundation hole, positioning the stub, and encasing it in concrete. Reinforcing steel cages would be assembled at laydown yards and delivered to each structure location by flatbed truck. Spoil material would be spread around the tower site and used for fill where suitable. The foundation excavation and installation would require access to the site by a power auger or drill, a crane, material trucks, and ready-mix trucks. Typical suspension structures would require approximately 25 to 40 cubic yards of concrete and dead-end structures would require approximately 120 cubic yards of concrete.

1.1.8 Tower Assembly and Installation

The size of the work areas for structures (assembly and installation sites) would be approximately 40,000 to 50,000 square feet (1 acre = 43,560 ft^2) depending on terrain. The location of these sites has not yet been determined, but exact locations would be identified within the COM Plan and POD prior to a Notice to Proceed from the agencies. Lattice towers would be assembled at each site, installed and bolted to the foundations. Bundles of steel members and associated parts would be transported to each tower site by truck. Steel members would be assembled into subsections of convenient size and weight on the ground. Assembly would be facilitated with a small rough-terrain crane. The assembled subsections would be erected into place by a large crane and then fastened together in the air to form a complete tower. See Figure 3 for an illustration of typical tower assembly and installation activities.

1.1.9 Conductor Installation

After the towers are erected, insulators, hardware, and stringing sheaves would be delivered to each tower site. The towers would be rigged with insulator strings and stringing sheaves at each ground wire and conductor position. Sheaves are rollers, temporarily attached to the lower end of the insulators that allow the conductor to be pulled, or "strung," along the line.

For public protection during wire installation, temporary guard structures would be built next to highways, railroads, power lines, structures, and other major obstacles. Guard structures would consist of

H-frame poles placed on either side of an obstacle. These structures would prevent ground wire, conductor, or equipment from falling on an obstacle. Equipment for installing guard structures would include augers, line trucks, pole trailers, and cranes. A guard structure would be anticipated to be necessary every five miles. The amount of ground disturbance would typically be 200 feet by 300 feet. The guard structures would be left in place until conductors and ground wires were strung, tensioned and clipped; this time frame would be approximately three weeks or longer depending on conditions. Guard structures may not be necessary for small roads. In such cases, other safety measures, such as barriers, flagmen, or other traffic control, would be used.

Pilot lines would be pulled (strung) from tower to tower by a helicopter and threaded through the stringing sheaves at each tower. The pilot line can be used to pull in the ground wire, but is used to pull in a larger-diameter, stronger pulling line for the conductor. The larger-diameter, stronger line—pulling line—would be attached to the conductors to pull them onto towers. This process would be repeated until the ground wire or conductor is pulled through all sheaves. Bundled conductors would be pulled together with the assistance of a running board. The running board attaches the bundled conductor to the pulling line.

Ground wire and conductors would be strung using powered pulling equipment at one end and powered braking or tensioning equipment at the other end of a conductor segment as shown on Figure 4. Sites for tensioning equipment and pulling equipment would be approximately 2.5 miles apart.

DISCLAIMER: FIGURE NOT TO SCALE

To the greatest extent practical, pulling and tensioning sites would be located within the transmission ROW. However, some pulling and tensioning sites may occur outside the ROW. The tensioning and pulling sites could be as large as 200 feet by 500 feet, however they would be limited in size depending on each specific location and what is reasonable for safe construction practices. The size of each site would be limited as much as possible and would be designed in coordination with the responsible property owner or land management agency. Depending on topography, some grading may be required at pulling and tensioning sites to create level pads for equipment. Tensioners, line trucks, wire trailers, and tractors needed for stringing and anchoring the ground wire or conductor would be located at the tensioning sites. A puller, line trucks, sag cat and tractors would be needed for pulling and temporarily anchoring the ground wire and conductor. Table 5 includes ground disturbance estimates for conductor installation (helicopter fly yards, portable helicopter landing pads, pulling and stringing sites, and sleeving and stringing operations).

After installing the conductor ground wire or fiber optic shield wire, sagging, clipping and dead-ending activities, terminating the conductors at dead-end structures, would be performed. This process would involve adjusting the position of the conductors and shield wires, removing stringing sheaves, and permanently attaching the conductor to the insulators with specialized hardware.

1.1.10 Counterpoise Installation and Grounding Practices

Part of standard construction practice prior to wire installation would involve measuring the resistance of tower footings and installation of counterpoise (grounds) as needed. To determine if a tower would require counterpoise, ground resistance measurements would be taken at towers sites after the installation of the foundations and structures. The measurements would be evaluated to determine the numbers and locations of structures requiring counterpoise. If the resistance to remote earth for each transmission tower is greater than 10 ohms, counterpoise (grounds) would be installed to lower the resistance to 10 ohms or less. Counterpoise would consist of a bare copper-clad or galvanized steel cable buried a minimum of 12 inches deep, extending horizontally from one or more tower legs for approximately 200 feet. Typical counterpoise installation would include two installations per structure on opposite tower legs. Four installations per tower could be required in certain circumstances.

In addition to counterpoise installation, standard grounding practices during construction would include both temporary and permanent grounding of equipment and structures, such as fences or pipelines, as necessary to reduce any potential magnetically induced voltages to harmless levels. Such practices could include electrical isolation of equipment or structures and the installation of grounding wires.

1.1.11 Switching Station Tie-in

At the proposed Haskell Canyon Switching Station, the transmission lines would be connected into and out of the switching station through dedicated station structures within the switching station, commonly referred to as "bus."

1.2 UPKEEP OF CONSTRUCTION SITES

Construction sites, material storage yards, and access roads would be kept in an orderly condition throughout the construction period. Refuse and trash would be removed from the sites and disposed of in an approved manner. Oils and fuels would not be dumped along the line. Oils or chemicals would be hauled to a disposal facility authorized to accept such materials. No open burning of construction trash would occur without agency approval.

Microtrash would be cleaned daily from all work areas within known California condor habitat. Microtrash is a term used to describe small bits of debris like bottle caps, rags, screws, bolts, wires, glass, and other materials found in condor habitat.

1.3 HAZARDOUS MATERIALS WITHIN THE PROJECT AREA

Petroleum products such as gasoline, diesel fuel, helicopter fuel, crankcase oil, lubricants, and cleaning solvents would be present within the Project area during construction. These products would be used to fuel, lubricate, and clean vehicles and equipment. These products would be containerized by fuel trucks or by approved containers. When not in use, hazardous materials would be properly stored to prevent drainage or accidents.

Hazardous materials would not be drained onto the ground or into streams or drainage areas. Totally enclosed containment shall be provided for all trash. All construction waste including trash and litter, garbage, other solid waste, petroleum products, and other potentially hazardous materials would be removed to a disposal facility authorized to accept such materials.

All construction, operation, and maintenance activities would comply with all applicable federal, state, and local laws and regulations regarding the use of hazardous substances.

The construction or maintenance crew foreman would insure that all applicable laws are obeyed. In addition, an on-site inspector would be present during construction to make sure that all hazardous materials are used and stored properly. A health and safety plan would be developed as part of the COM Plan and POD during the engineering and preconstruction phase of the Project.

1.4 SITE RECLAMATION

The ROW, including temporary construction sites, and any temporary ground disturbance outside of the ROW that may have been caused during or due to the construction of the Project (e.g., temporary access roads, staging sites, assembly yards) would be restored as required by the property owner or land management agency. All practical means would be used to restore the land to its original contour and to restore natural drainage patterns along the ROW. Because revegetation would be difficult in many areas of the Project where precipitation is minimal, it would be important to minimize disturbance during construction. All practical means would be used to increase the chances of vegetation reestablishment in disturbed areas.

The total construction period would be approximately two years. The COM Plan that would be completed during the engineering and preconstruction phase of the Project would address specific site reclamation of all disturbed areas.

1.5 FIRE PROTECTION

A Fire Management Plan would be developed for the Project and all applicable fire laws and regulations would be observed during the construction period. All personnel would be advised of their responsibilities under the applicable fire laws and regulations, including taking practical measures to report and suppress fires.

1.6 CONSTRUCTION MONITORING

An approved compliance program would be developed to address mitigation requirements associated with the avoidance of sensitive plant and animal species, cultural sites, or other sensitive features located

within or adjacent to the Project. Prior to construction, these measures will be described in detail and included in the POD.

1.7 THREE-CIRCUIT TOWER MITIGATION

A temporary transmission line would be constructed to keep the BR-RIN circuit energized during construction of the three-circuit towers. After the temporary line is constructed, the existing BR-RIN single-circuit towers would be removed to allow the new three-circuit towers to be constructed within the existing ROW. Once construction of the three-circuit towers is completed, the temporary transmission line would be removed.

The temporary transmission line would be 7.5 miles long and would consist of wood and steel single poles with an average height of 95 feet, a 3-foot by 3-foot footprint, and an average of eight poles per mile. Construction would occur within a temporary 80- to 100-foot ROW. Refer to Table 4 for specifications and to Table 5 for ground disturbance estimates. The majority of the temporary transmission line would be constructed along San Francisquito Road. Portions would also be constructed along Elizabeth Lake Road and Johnson Road. Pole placement would be adjacent to public roadways wherever possible. If necessary, temporary ROW on private property would be needed where poles could not be placed within public road ROW. The majority of poles would be direct-embedded when set in place and would not require a permanent foundation. Where additional strength is necessary at larger angle points, steel poles would be required, which could require an excavation approximately 6 feet in diameter by 20 feet deep to accommodate the concrete pier foundation that would be cast in place. Once all the poles have been constructed and the conductor installed, the existing BR-RIN circuit would be connected into the temporary line and energized. The construction would require establishment of a staging area, work areas around poles, and pull and tension sites. Access to pole sites and pull and tension sites would be from the adjacent roadways.

Approximately seven miles of the existing BR-RIN single-circuit towers would be removed, with existing ROW utilized to access the existing towers. The new three-circuit towers would be placed within the existing ROW, utilizing existing access roads. Helicopter Mitigation, as described in this section below, would be applied in steeper terrain crossing the Angeles National Forest if additional access is required. If additional access roads, considered to be longer than 300 feet, are necessary, specific locations and construction method (either helicopter or conventional) would be coordinated with the USFS. The new three-circuit tower would require a 25-foot by 30-foot structure footprint and an average of seven structures per mile; the average structure height would be 170 feet, with a maximum tower-to-tower span length of 780 feet. Structures would be installed in the same locations as the existing BR-RIN structures within the limits of standard tower design. The construction process for the new three-circuit towers would be the same as the double-circuit towers discussed above. After completion of construction of the three-circuit towers, the temporary transmission line would be removed and all temporary staging and work area land disturbances would be restored as close to previous conditions as possible and revegetated as required. Restoration practices would be consistent with Section 1.11 Decommissioning of Transmission Lines.

TABLE 4. THREE-CIRCUIT TOWER SPECIFICATIONS

Tower Placement Details	Specifications	
	Triple-Circuit	Temporary Transmission Line
ROW acquisition	None (within existing)	80-100 ft
Structures per Mile	7	8
Average span length	750 ft	650 ft

Tower Placement Details	**Specifications**	
	Triple-Circuit	**Temporary Transmission Line**
Average height (ft) Ground to lowest attachment	120	60
Upper body height	50	45
Overall tower height	170	105
Typical range of heights of new towers	150 - 180 ft.	95 - 105 ft.

1.8 HELICOPTER MITIGATION

The following sites and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas and associated temporary access roads, tower structure vegetation clearing, guard structures at major crossings, and access road pullouts. Refer to Table 5 for ground disturbance estimates for the Helicopter Mitigation.

The transmission line materials (tower steel, conductor reels, structure hardware, etc.) would be delivered by truck to the helicopter fly yards/staging areas. Vegetation clearing may be required at these sites to ensure safe working conditions. The fly yards/staging areas would serve as helicopter support yards for fueling and maintenance, as well as for the transport of materials and personnel. Towers may also be assembled in sections at these yards prior to delivery to the tower sites. Heavy lift helicopters would then fly the towers from the yards to the tower sites.

Portable landing pads would be located at each tower site. These pads would allow helicopters to load and unload personnel, tools, and equipment necessary for construction of foundations and assembly of tower structures. Helicopter-constructed towers that would not be in close proximity to existing access roads would utilize micropile foundations. For each tower leg, micropile foundations would use a group of three to eight 6- to 9-inch diameter casings that would be drilled and grouted into the ground. The exposed portion of the pile group would be encased in a reinforced concrete cap from the top of the casings to a depth anywhere from one to eight feet below the ground surface, depending on the terrain. Figure 5 illustrates the plan view and sections of a micropile foundation.

SUPPORT

Conductor installation would proceed as for double-circuit tower installation. The equipment necessary for conductor installation would be large, heavy construction equipment that could only be brought in by truck. Some NFS roads could need maintenance or improvement to allow pulling and tensioning, but no new access or spur roads would be created for conductor installation on the helicopter-constructed towers.

Information based on LADWP and POWER Engineers, Inc. estimates. Actual disturbance areas may be smaller based on final engineering design.

---

[1] For slopes over 10% (ground disturbance categories 4-6), site dimensions would be 200 x 250 ft. (1.2 acres) and have an average disturbance of 5.8 acres per mile.
[2] For slopes over 10% (ground disturbance categories 4-6), sites would be every 2 miles and have an average disturbance of 1.2 acres per mile.
[3] Access and spur road disturbances included in Table 1.
[4] Ibid.

THIS PAGE INTENTIONALLY LEFT BLANK

1.9 OPERATION OF TRANSMISSION LINES

The nominal voltage for the BRRTP transmission line would be 230 kV AC. There may be minor variations of up to five percent above the nominal level depending upon load flow.

1.9.1 Permitted Uses

After the transmission line has been energized, land uses that are compatible with safety regulations (such as agriculture and grazing) would be permitted in and adjacent to the right-of-way. Incompatible land uses within the right-of-way include construction and maintenance of inhabited dwellings, and any use requiring changes in surface elevation that would affect electrical clearances of existing or planned facilities.

Land uses on public lands that comply with local regulations would be permitted adjacent to or within the ROW, with require approval from the appropriate agency. Permission to use the ROW on private lands would have to be obtained from the utility owning the transmission line.

1.9.2 Safety

Safety is a primary concern in the design of this 230 kV transmission line. The AC transmission line would be protected with power circuit breakers and related line relay protection equipment. If conductor failure occurs, power would be automatically removed from the line. Lightning protection would be provided by overhead ground wires along the line. Electrical equipment and fencing at the switching station would be grounded. All fences, metal gates, pipelines, and other metal components that cross or are within the transmission line ROW would be grounded to prevent electrical shock. If applicable, grounding outside of the ROW may also occur.

1.10 MAINTENANCE OF TRANSMISSION LINES

The 230 kV transmission line would be inspected several times annually by both ground and air patrols. Maintenance would be performed as needed. When access is required for non-emergency maintenance and repairs, LADWP would adhere to the same precautions and procedures that were taken during the original construction.

Emergency maintenance would involve prompt movement of repair crews to repair or replace any damaged equipment or infrastructure. Crews would be instructed to protect crops, plants, wildlife, and other resources of significance. Restoration procedures following completion of repair work would be those prescribed for project implementation construction. The comfort and safety of local residents would be provided for by limiting noise, dust, and the danger caused by maintenance vehicle traffic. Details would be provided in the COM Plan and POD prior to line construction.

1.10.1 Vegetation Management

Vegetation management along the transmission line ROW would be required by the North American Reliability Council (NERC). In compliance with the NERC's Standard FAC-003-l, LADWP would prepare a Vegetation Management Plan for the BRRTP. The Vegetation Management Plan would be included in the COM Plan to be completed prior to the issuance of a Notice to Proceed from the USFS and BLM. Vegetation management would consist of routine tree trimming to maintain the required minimum 10-foot clearance from conductors to vegetation (California Public Resources Code [PRC] 4293); clearance of flammable brush vegetation within a 10-foot radius around the base of transmission line towers in accordance with California PRC 4292; and clearance immediately adjacent to access roads to permit adequate access to the facilities.

1.10.2 Access Road Maintenance

Ongoing access road maintenance would be conducted in accordance with existing or new road authorizations issued to LADWP. Access road maintenance consists of those activities necessary to allow continued access to the ROW and/or each tower structure. These activities may include grading, and maintenance of drainage systems, bridges, culverts, fences, gates and signs. Motor graders, backhoes, dump trucks and pickups are used to maintain access roads.

1.11 DECOMMISSIONING OF TRANSMISSION LINES

At the end of the useful life of the proposed Project, if the facility were no longer required, or if extension of the authorizations were not granted by federal land agencies at the time they expired, the transmission line would be abandoned. Subsequently, conductors, insulators and hardware would be dismantled and removed from the ROW. Tower structures would be removed and foundations broken off below ground surface.

If the line and associated ROW are abandoned at some future date, the ROW would be available for the same uses that existed prior to construction of the Project. Following abandonment and removal of the transmission line from the ROW, any areas disturbed to dismantle the line would be restored and rehabilitated as near as possible to their original condition.

2.0 ADDITION OF NEW 230 KV CIRCUIT

Between the proposed Haskell Canyon Switching Station and the existing Castaic Power Plant, LADWP proposes the addition of 12 miles of a new 230 kV transmission circuit onto existing Castaic – Olive 230 kV Transmission Line structures (towers 1-1 through 12-1). This new circuit would be called Castaic – Haskell Canyon #4 and would utilize the same conductor (2,156 kcmil "Bluebird" ACSS/AW) as that proposed for the new 230 kV transmission line between Barren Ridge and Haskell Canyon Switching Stations.

The addition of a new circuit on existing towers would require many of the same activities of a new transmission line (surveying of ROW, rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, and cleanup). However, all work would be within existing ROW and no new towers would be constructed. Some towers may need to be modified or reinforced to carry the additional weight of the new conductor. Specific towers requiring reinforcement would be determined following detailed design of the Project. Tower reinforcement would not alter the general design or the location of the structures. This process would generally include reinforced foundations or steel member replacements.

3.0 RECONDUCTORING

LADWP proposes the reconductoring of 76 miles of the existing BR-RIN 230 kV transmission line with larger conductors between the Barren Ridge Switching Station and Rinaldi Substation (towers 176-1 through 251-1). The existing conductors (954/ 2,312 kcmil) would be replaced with a new 1,433.6 kcmil "Merrimack" ACSS/TW/HS conductor. The new conductor would have a larger diameter that allows for greater electrical capacity.

The upgrade of the existing BR-RIN would also require many of the same activities of the new transmission line (surveying of ROW, rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, and cleanup). Removal of the existing conductor would be used to string a pulling line, and this line would then be used to pull in the new conductor. All work would remain within the existing 250-foot-wide ROW, with no additional ROW required. Some of the towers would need to be

modified, replaced, and/or have foundations reinforced or replaced to carry the additional weight of the new heavier conductor.

4.0 NEW HASKELL CANYON SWITCHING STATION

As a component of the BRRTP, LADWP proposes the construction of a new switching station in Haskell Canyon, south of the Angeles National Forest on LADWP-owned property at the convergence of several existing and proposed 230 kV transmission lines (the existing BR-RIN, the proposed double-circuit Barren Ridge-Haskell Canyon, existing Castaic-Northridge, Castaic-Sylmar, Castaic-Olive, and the proposed Castaic to Haskell Canyon).

The station would be approximately 500 feet by 600 feet to accommodate the necessary circuit positions, which are made up of equipment, such as steel support structures, circuit breakers, disconnect switches, and associated equipment, and a relay house and control house containing control and protective relaying equipment. The relay and control houses would each be approximately 30 feet long by 12 feet wide by 10 feet high and constructed of gray concrete block. The station yard would include a paved internal access road approximately 16 feet wide and would be enclosed by chain-link fencing with barbed-wire extension for security. Figure 6 illustrates the preliminary design layout for the station. Figure 7 illustrates the preliminary grading plan for the station.

Necessary pre-construction geotechnical investigation on-site would include six borings by a drill rig to investigate bedrock and soil stability and four cone penetration test locations after site grading to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

Construction of the new Haskell Canyon Switching Station would consist of preconstruction surveys, clearing and grading of access roads, site grading and drainage development, installation of concrete foundations and steel support structures, installation of below- and above-ground electrical conduits for equipment power and control, installation of below- and above-grade grounding conductors, and installation of control and relay houses. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks, and flatbed trailers. Cranes, man-lifts, portable welding units, line trucks, and mechanic trucks would also be required. Construction would require an estimated 12 months with approximately 60 workers.

Site preparation work for the station would involve clearing and grading of access roads, clearing of the switchyard site, the cut and fill grading of the site, and placement and compaction of structural fill that would serve as a base for switching station facilities. The site would be graded to maintain current drainage patterns as much as possible. A 16-foot wide paved road and 100-foot by 100-foot gravel parking area would be required. The yard would be covered with crushed-rock aggregate. Native vegetation would be re-established where possible outside the switchyard fence.

Following site grading and development, reinforced concrete foundations would be installed to support the steel structures and electrical equipment and control facilities. It is estimated that 1,500 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 180 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 120-day working period. Subsequent to the foundation installation, trenches would be dug to facilitate placement of copper conductors for the station grounding mat.

Multiple transmission lines would be terminated into the switching station (i.e., the new and existing Barren Ridge – Haskell and Castaic – Haskell Canyon transmission lines) and would need support and

require the installation of galvanized steel structures. An existing 115 kV transmission line may need to be relocated around the proposed station. High-voltage bus work consisting of aluminum jumpers and tubing would be installed within the station.

PRELIMINARY IMPROVED ACCESS ROAD SUMMARY:

ROAD LENGTH	3,800 FT
ROAD WIDTH	
EXISTING	14 FT
PROPOSED	22 FT
MAXIMUM SLOPE	15 %
MINIMUM CENTERLINE RADIUS OF CURVES	80 FT

NOTES:

THE ALIGNMENT OF THE PROPOSED PAVED ACCESS ROAD FOLLOWS THAT OF THE EXISTING PATROL ROAD.

THE EXISTING ACCESS ROAD WILL NEED TO BE WIDENED AND PAVED TO ALLOW SERVICE VEHICLES ACCESS TO THE PROPOSED STATION. WIDENING THE ROAD WILL REQUIRE ADDITIONAL GRADING AND EARTHWORK.

THE PROPOSED ACCESS ROAD MAY BE SUBJECT TO THE APPROVAL THE LOS ANGELES COUNTY FIRE DEPARTMENT.

THE EARTHWORK QUANTITIES AND CONSTRUCTION COST ESTIMATES LISTED ON SHEET 1 DOES NOT INCLUDE THE CONSTRUCTION OF THE IMPROVED ACCESS ROAD.

IN THIS ALTERNATIVE, THE PROPOSED STATION EXTENDS INTO PRIVATE PROPERTY. RIGHTS TO THIS PRIVATE PROPERTY MUST BE ACQUIRED BY LADWP.

PLEASE NOTE THAT THIS DESIGN IS PRELIMINARY. THE TOPOGRAPHY, PROPRETY LINES, PROJECT LIMITS AND DESIGN VARIABLES ARE APPROXIMATE AND THUS SUBJECT TO CHANGE. A NUMBER OF REMAINING ENGINEERING AND ENVIRONMENTAL ISSUES MUST STILL BE RESOLVED. THIS EXHIBIT, AND CORRESPONDING CONSTRUCTION COST ESTIMATE, ARE FOR PRELIMINARY SITE EVALUATION PURPOSES ONLY.

5.0 EXPANSION OF BARREN RIDGE SWITCHING STATION

LADWP proposes expansion of the existing Barren Ridge Switching Station to the east side by 235 feet by 500 feet, for a total station size of 485 feet by 500 feet (approximately 5.6 acres). The expansion area of the station would include electrical structures and equipment for the addition of transmission lines, a material staging area, roadway within the station, and drainage area. Figure 8 illustrates the preliminary design layout for the station.

Expansion of the existing switching station would be very similar to the construction of the Haskell Canyon Switching Station as described above. Expansion would consist of preconstruction surveys, site preparation and grading, installation of reinforced concrete foundations, installation of electrical conduits for equipment power and control, and installation of structures and equipment.

Necessary pre-construction geotechnical on-site investigation would include two test pits excavated by a backhoe to investigate soil density and settlement, and four cone penetration test locations on-site to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

It is estimated that 700 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 80 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 90-day working period. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks and flatbed trailers. Cranes, man-lifts, portable welding units, line

trucks, and mechanic trucks would also be required. An estimated 8 months with approximately 60 workers would be required to expand the station.

1.0 INTRODUCTION

The City of Los Angeles Department of Water and Power (LADWP) is proposing the Barren Ridge Renewable Transmission Project (BRRTP or Project) to access clean, renewable resources in the Tehachapi Mountains and Mojave Desert areas, and to improve reliability and upgrade transmission capacity.

LADWP, the US Department of Agriculture, Forest Service (USFS or Forest Service) and the U.S Department of the Interior, Bureau of Land Management (BLM) are preparing a joint Environmental Impact Statement (EIS) / Environmental Impact Report (EIR) for the proposed BRRTP. LADWP is the California Environmental Quality Act (CEQA) Lead Agency, while the USFS and BLM are the federal Co-Lead Agencies under the National Environmental Policy Act (NEPA). An EIS/EIR is an informational disclosure document used to inform agency decision makers and the public of the potential significant environmental effects of a project, identify possible ways to eliminate or minimize the potential significant effects, and describe reasonable alternatives to the Proposed Action /Project.

The purpose of the water resources study is to inventory existing water resources and assess the potential impacts to water resources of each of the proposed transmission line alternative corridors (segments), proposed switching station, and expansion of the existing switching station. The water resource environmental analysis will:

- present the regulatory framework
- provide an overview of the technical methodology used in collecting baseline conditions and evaluating impacts
- examine the affected environment within the study corridors and vicinity, where appropriate
- describe the potential impacts on water resources resulting from construction and operation of the Project
- evaluate the level of potential impacts based upon National Environmental Policy Act (NEPA)/California Environmental Quality Act (CEQA) criteria
- present specifically recommended mitigation measures to minimize potential impacts.

1.1 STUDY PERSONNEL

POWER Engineers, Inc. (POWER) personnel who compiled data for background research and prepared the water resources technical report included Allison Carver, a biologist with over 10 years professional experience in biology and water resources, and Kirsten Severud, who provided GIS support for the Project.

1.2 PROJECT DESCRIPTION

The BRRTP would be located in Kern and Los Angeles counties. As proposed by LADWP, it would be approximately 76 miles in length extending from the Barren Ridge Switching Station to Rinaldi Substation, and extending approximately 12 miles from the Castaic Power Plant to the proposed Haskell Canyon Switching Station. As shown in Figure 1-1, the proposed BRRTP would include the following:

1) Construction of approximately 61 miles of a new 230 kilovolt (kV) double-circuit transmission line from the LADWP Barren Ridge Switching Station to Haskell Canyon;
2) Addition of approximately 12 miles of a new 230 kV circuit on the existing double-circuit structures from Haskell Canyon to the Castaic Power Plant;
3) Reconductoring of approximately 76 miles of the existing Barren Ridge-Rinaldi (BR-RIN) 230 kV transmission line with larger capacity conductors between the Barren Ridge Switching Station and the Rinaldi Substation;
4) Construction of a new switching station in Haskell Canyon;
5) Expansion of the existing Barren Ridge Switching Station.

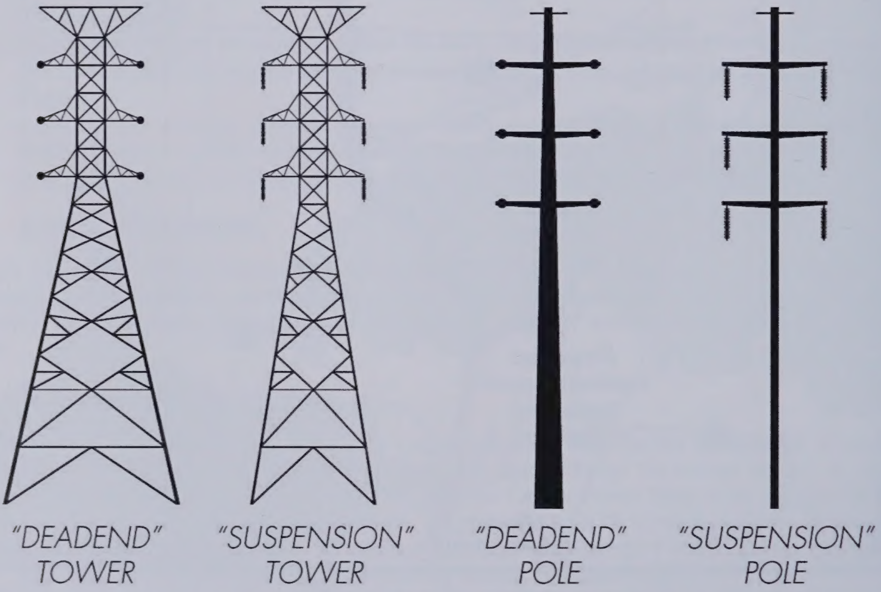
1.2.1. Construction of New 230 kV Double-Circuit Transmission Line

The proposed double-circuit 230 kV transmission line component of the BRRTP would consist of two alternating current (AC) circuits from the Barren Ridge Switching Station to the proposed Haskell Canyon Switching Station in Haskell Canyon.

The proposed structures for the new transmission line would primarily be self-supporting double-circuit steel lattice towers fabricated from galvanized steel members, as shown on the left side of Figure 1-2. Depending on the environmental conditions of the surrounding terrain, the height of the proposed lattice structures would range from 110 to 195 feet, with an average tower-to-tower span of 1,000 to 1,100 feet. Appendix C lists the structure specifications for the number of structures per mile, average span length, and average heights for towers and components. Exact structure placement would be determined during engineering surveys and detailed design studies for the selected Alternative route following the Record of Decision (ROD) on the EIS/EIR. A variety of engineering, constructability, existing access, and environmental issues would be considered during detailed structure siting within the permitted ROW.

"Dead-end" towers of self-supporting, steel-lattice design would be required periodically to add longitudinal strength along the line. Dead-end towers would also be used at turn (angle) locations along the line, at heavily loaded tower locations, and at specific utility crossings (e.g., other transmission lines) for added safety. Dead-ended towers are of the same basic configuration as suspension towers (non-angle structures), the difference being in the tower "arms," insulator systems, and tower weights.

FIGURE 1-2. TYPES OF TOWERS



Self-supporting, tubular steel poles (TSP) have been proposed by LADWP as an available mitigation structure where appropriate to reduce potential impacts, such as conflicts with cultivation on agricultural lands. The TSPs can reduce impacts in some cases due to a smaller footprint than the proposed self-supporting steel lattice structures; however, more TSPs per mile are necessary due to a shorter average span between structures. The TSPs would have an average height range between 95 and 180 feet, depending on the conditions of the surrounding terrain, with an average tower-to-tower span of 700 to 800 feet. Refer to Figure 1-2 for an illustration of the double-circuit poles.

For the majority of the alignment, the two new 230 kV circuits would be placed on new double-circuit transmission towers, but for approximately 1.5 miles, the circuits would be placed on existing four-circuit structures that are located just north of the proposed Haskell Canyon Switching Station. Between where the existing BR-RIN crosses Dry Canyon to the intersection of the Castaic transmission lines, LADWP has existing four-circuit towers with three vacant positions. The existing towers would be utilized in this section for the proposed 230 kV double circuit transmission line instead of constructing new towers. See Figure 1-3 for the location and illustration of the existing four-circuit towers to be utilized.

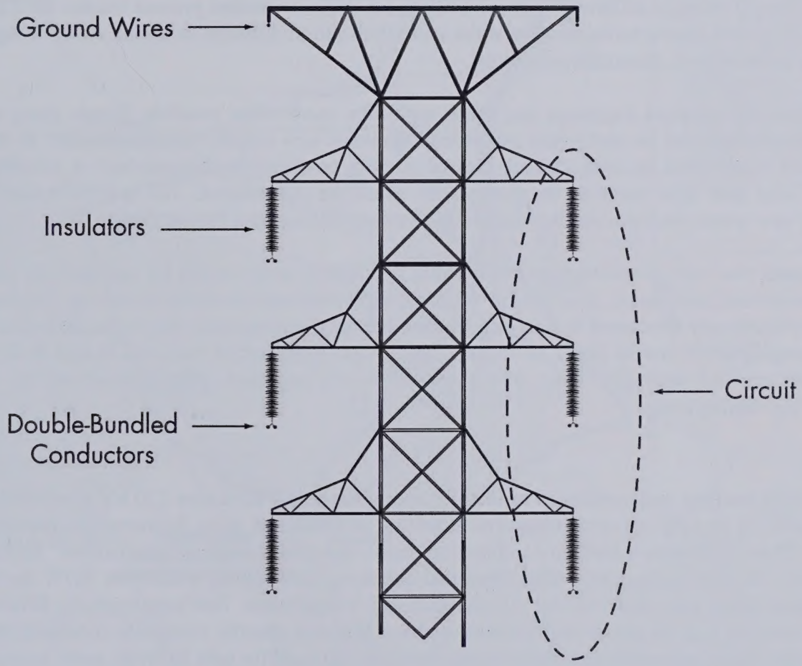
BARREN RIDGE RENEWABLE TRANSMISSION PROJECT

The self-supporting steel lattice structures and TSPs would utilize concrete foundations. Steel lattice structures would require four footings (one for each leg); TSPs would require single footings. Footings would be steel-reinforced concrete pier type and be cast in place. The typical design for the concrete footings for lattice structures would be between 2.5 and 5.0 feet in diameter, with an average depth of 20 feet depending on soil conditions. Typical design for single foundations for TSPs would include augured holes approximately five to seven feet in diameter and 15 to 30 feet deep, depending on conditions. Formwork steel reinforcing would be assembled in the hole prior to casting concrete in place. Reinforcing steel would become integral to the lower leg of the steel lattice structure during assembly. An above-ground concrete form placed over each hole would result in a final concrete foundation height of 0.5 to 2.0 feet above ground level.

As illustrated in Figure 1-4, Typical Tower Components, each tower carries conductors ("wires"), insulators, and ground wires. The conductor being considered for the new double-circuit 230 kV transmission line and installation of the Castaic – Haskell Canyon #4 circuit on existing structures is a bundled 715.5 kcmil "Starling" ACSS/AW. The reconductoring of the BR-RIN transmission line between Barren Ridge Switching Station and Rinaldi Substation would require a bundled 1,433.6 kcmil "Merrimack" ACSS/TW/HS conductor.

FIGURE 1-4. TYPICAL TOWER COMPONENTS



Each circuit would consist of three phases ("wires") as illustrated in Figure 1-4. To increase the current-carrying capability of the transmission lines and reduce power loss, the Proposed Action (Alternative 2) would utilize bundled conductors installed for each phase. The bundled conductors would consist of two conductor cables connected by a spacer. The new 230 kV double-circuit transmission line would consist of a total of six double-bundled (12 individual) wires.

Minimum conductor height above the ground, under normal operation of the line, is 30 feet. Greater clearances may be required in certain areas to allow for clearances over trees or other vegetation that

could pose a risk to the operation of the transmission line. Minimum conductor clearance would dictate the exact height of each tower based on topography and safety clearance requirements.

Insulators are used to provide the physical connection of conductors to structures. These system components are made of very low conducting materials (polymer insulators) that inhibit the flow of electric current from energized conductors to ground or to other energized system elements. Insulators and their associated hardware are to be configured in an "I" assembly to support conductors while maintaining required distances between phases and grounded structures. Each "I" string would consist of six-inch diameter insulators between six and eight feet long.

To shield conductors from hazard of direct lightning strikes by transferring lightning currents into the ground, overhead ground wires (shield wires) or fiber optic ground wire would be installed on top of new structures.

Construction of a transmission line involves the following general sequence of events: surveying activities; identifying and constructing access roads; clearing ROW and tower sites (including construction yards and batch plants); installing foundations; assembling and installing the towers; clearing, pulling, tensioning, and splicing; installing ground wires and conductors; installing counterpoise; switching station tie-in; and site upkeep and site reclamation. Various phases of construction would occur at different locations throughout the construction process for the BRRTP. This would require several contractors operating at the same time and in different locations. Refer to Appendix C for a description of each construction activity.

Existing paved and unpaved highways and roads would be used where possible. Roads along existing utility corridors would also be used where possible to minimize new access road construction. In locations where existing roads could be used, that are located in close proximity to the proposed or existing ROW centerlines, only new spur roads to the tower sites would be constructed. The specific locations and design of all new access and spur roads would be determined during final Project design.

It is anticipated that one or two construction yards or staging areas would be required for materials storage, construction equipment, construction vehicles, and temporary construction offices. Staging areas would be approximately five acres in size, and located centrally or near each end of the transmission line route. The staging areas would likely be located on previously disturbed land and would be level and surfaced with crushed aggregate base. The LADWP would negotiate with landowners for specific locations of the staging areas.

Routing

In 2007, a siting analysis was conducted to identify appropriate sites for a new 230 kV transmission line. Over 200 miles of routing opportunities were identified and referred to as Segments A through I (see Figure 1-5). These segments were then combined to create end-to-end routing "alternatives" as discussed in Section 8.2. All routing Segments were identified assuming the need for a 200-foot ROW for the new 230 kV transmission line and the use of conventional transmission line construction. However, as discussed in Section 8.2, the end-to-end alternatives have included specific mitigation measures to reduce certain impacts. These mitigation measures would eliminate the need for new ROW in some locations and would require the use of helicopters for tower assembly in designated areas on the ANF. Also, to the maximum extent possible, all existing access and spur roads would be utilized for the construction, operation, and maintenance of the BRRTP. Below is a brief description of each segment.

Segment A is 13 miles long and runs from LADWP's Barren Ridge Switching Station to the unincorporated community of Mojave, California. It would traverse four miles of BLM managed public lands and parallel LADWP's existing 230 kV Barren Ridge – Rinaldi Transmission Line (BR-RIN) and the 500 kV Pacific Direct Current Intertie (PDCI). It traverses four miles of BLM-managed lands.

Segment B is 27 miles long and starts just north of the unincorporated community of Mojave, California and travels south to a point one mile east of the Antelope Valley California Poppy Reserve. This segment parallels LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines for its entire length.

Segment C is 22 miles long and begins at the location as Segment B, north of the unincorporated community of Mojave, California. Segment C parallels the Los Angeles Aqueduct in a southwest direction to Cottonwood Creek. No existing transmission lines are located within the aqueduct corridor; however, Southern California Edison's (SCE's) Tehachapi Renewable Transmission Project's (TRTP) Alternative 10A is also proposed along the same corridor.

Segment D is 48 miles long and would traverse 16 miles of National Forest System (NFS) lands. This segment generally parallels the Los Angeles Aqueduct in a southwest direction, beginning near Cottonwood Creek and traveling to Lancaster Road. It then travels west to the Interstate 5 freeway utility corridor and continues southeast along LADWP's existing Castaic – Rinaldi corridor to the proposed Haskell Canyon Switching Station. Five high voltage transmission lines are located along the Interstate 5 section of the segment. Oil and gas pipelines are also located in the same I-5 corridor. Continuing further south near Castaic Power Plant, Segment D would be located to the south of two existing LADWP double-circuit 230 kV transmission line towers until reaching the proposed Haskell Canyon Switching Station.

Segment E is 11 miles long and begins near Cottonwood Creek at the intersection of Segments C and D. Segment E travels in a southeast direction and intersects Segment B one mile east of the Antelope Valley California Poppy Reserve. Three existing high voltage transmission lines (Midway-Vincent 500 kV, Antelope-Vincent 230 kV, and Antelope-Mesa 230 kV) are located within the corridor that Segment E would parallel. SCE's proposed TRTP Segment 4 is also proposed adjacent this same corridor.

Segment F is the shortest segment, at four miles in length, and begins at the intersection of Segments B and E one mile east of the Antelope Valley California Poppy Reserve. Three existing high voltage transmission lines (Midway-Vincent 500 kV, Antelope-Vincent 230 kV, and Antelope-Mesa 230 kV) are also located parallel to this segment.

The 115th Street Segment was proposed as a modification to avoid impacts to residents in the Antelope Valley near Segments F and H, described below. It begins mid-way within Segment F near SCE's Antelope Substation and parallels 115th Street south to the California Aqueduct. No existing transmission lines occur within this corridor; however, TRTP's proposed Segment 4 would be located along this alignment. This segment would split Segments F and H as shown in Figure 1-5 creating these Segments into F1, F2, H1 and H2.

Segment G is 21 miles long. Thirteen miles traverse National Forest System (NFS) lands. It travels south from the intersection of Segments B and F one mile east of the Antelope Valley California Poppy Reserve to the proposed Haskell Canyon Switching Station, located near the southern boundary of the ANF. It is a designated utility corridor containing LADWP's existing 230 kV BR-RIN and 500 kV PDCI lines. The BRRTP proposes to use its existing four-circuit structures for two miles, from towers 234-3 to 236-2 (see Figure 1-3).

Segment 2a is seven miles long. It would bypass the unincorporated community of Green Valley and follow an existing fire road through ANF. Segment 2a would not parallel existing transmission facilities, and a new utility corridor would be required.

Segment H is 20 miles long and would parallel SCE's Antelope-Pardee line. It starts near SCE's Antelope Substation at the intersection of Segments F and I and traverses 13 miles of NFS lands to the proposed Haskell Canyon Switching Station. As requested by the USFS, all portions of this segment that fall within the northern and southern borders of the ANF would be constructed entirely by the use of helicopters. The helicopter construction requirement was established by the USFS for consistency of transmission line construction within the existing Antelope-Pardee transmission line corridor. No new access roads would be constructed except those required for pulling and tensioning sites or staging locations for construction materials. The addition of the 115th Street Segment, described above, splits the Segment into H1 (northern portion) and H2 (southern portion).

Segment I is 32 miles long. It begins near the Antelope Substation at the intersection of Segments F and H, and heads southeast through the City of Palmdale, parallel SCE's existing high voltage transmission lines (Midway-Vincent 500 kV, Antelope-Vincent 230 kV, and Antelope-Mesa 230 kV). The segment continues directly south to an existing LADWP transmission line corridor, then continues in a southeast direction to the proposed Haskell Canyon Switching Station, parallel LADWP's existing high voltage transmission lines (Victorville-Rinaldi 500 kV and Adelanto-Rinaldi 230 kV). A majority of this segment would be located outside of NFS lands. Two miles would be located on NFS lands.

Segment J is located parallel to the southern portion of Segment D. Segment J would consist of a new single 230 kV circuit to be placed on existing double-circuit towers between Castaic Power Plant and the proposed Haskell Canyon Switching Station (see discussion in Section 1.2.2 below).

Three-Circuit Tower Mitigation

In areas where there are ROW expansion constraints and where LADWP has existing 230 kV transmission lines, LADWP is proposing to construct three-circuit towers within the existing ROW to carry the existing BR-RIN circuit and the two proposed Barren Ridge to Haskell Canyon (BR-HC) circuits. This would avoid various impacts, including the acquisition of residential property in the unincorporated communities of Willow Springs (milepost 27.1 to 27.6) and Elizabeth Lake and Green Valley (milepost 44.6 to 51.7). Refer to Figure 1-6 for an illustration of three-circuit tower types, and to Figure 1-7, the Three-Circuit Tower Mitigation Map, for proposed locations.

POWER ENGINEERS
LA DWP

LADWP must maintain the electrical service along the existing BR-RIN transmission line to avoid impacts to the hydroelectric power plants north of the Barren Ridge Switching Station. Therefore, a temporary transmission line would be constructed to keep the BR-RIN circuit energized during construction of the three-circuit towers. After the temporary line is constructed, the existing BR-RIN single-circuit towers would be removed to allow the new three-circuit towers to be constructed within the existing ROW. Once construction of the three-circuit towers is completed, the temporary transmission line would be removed. The temporary transmission line is expected to be in place from six to nine months.

The temporary transmission line would be 7.5 miles long and would consist of wood and steel single poles with an average height of 95 feet, a 3-foot by 3-foot footprint, and an average of eight poles per mile. Construction would occur within a new temporary 80- to 100-foot ROW. The majority of the temporary transmission line would be constructed along San Francisquito Road. Portions would also be constructed along Elizabeth Lake Road and Johnson Road. Pole placement would be adjacent to public roadways wherever possible. If necessary, temporary ROW on private property would be needed where poles could not be placed within public road ROW. The majority of poles would be direct-embedded when set in place and would not require a permanent foundation. Where additional strength is necessary at larger angle points, steel poles would be required, which could require an excavation approximately 6 feet in diameter by 20 feet deep to accommodate the concrete pier foundation that would be cast in place. Once all the poles have been constructed and the conductor installed, the existing BR-RIN circuit would be connected into the temporary line and energized. The construction would require establishment of a staging area, work areas around poles, and pull and tension sites. Access to pole sites and pull and tension sites would be from the adjacent roadways.

Approximately seven miles of the existing BR-RIN single-circuit towers would be removed, with existing ROW utilized to access the existing towers. The new three-circuit towers would be placed within the existing ROW, utilizing existing access roads. Helicopter Mitigation, as described in this section below, would be applied in steeper terrain if additional access is required. The new three-circuit tower would require a 25-foot by 30-foot structure footprint and an average of seven structures per mile; the average structure height would be 170 feet, with a maximum tower-to-tower span length of 780 feet. The construction process for the new three-circuit towers would be the same as the double-circuit towers discussed above. After completion of construction of the three-circuit towers, the temporary transmission line would be removed and all temporary staging and work area land disturbances would be restored as close to previous conditions as possible and revegetated as required.

Helicopter Mitigation

Within the ANF where the terrain is steep and access is limited, the USFS would require that the new double-circuit 230 kV structures be constructed with the use of helicopters (such as the Hughes 500 or Bell 212, or Sikorsky Skycrane). Although no specific locations for this mitigation have been identified for the Proposed Action, as defined, it is expected USFS would require the helicopter mitigation for construction in any area more than 300 feet from an existing road and with slopes greater than approximately 25 percent. The use of helicopters for the construction of transmission tower structures would eliminate the need for new access roads to structure locations, and would therefore minimize land disturbance associated with crane pads, structure laydown areas, and the trucks and tractors used for delivery of structures to sites. However, the following site and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas and associated access roads, tower structure vegetation clearing, guard structures at major crossings, and access road pullouts.

Temporary 24-foot wide access roads would be required to access the helicopter fly yards/staging areas. The transmission line materials (tower steel, conductor reels, structure hardware, etc.) would be delivered by truck to the helicopter fly yards/staging areas. Vegetation clearing may be required at these sites to ensure safe working conditions. The fly yards/staging areas would serve as helicopter support yards for fueling and maintenance, as well as for the transport of materials and personnel. Towers may also be assembled in sections at these yards prior to delivery to the tower sites. Heavy lift helicopters would then fly the towers from the yards to the tower sites.

Portable landing pads would be located at each tower site. These pads would allow helicopters to load and unload personnel, tools, and equipment necessary for construction of foundations and assembly of tower structures. Helicopter-constructed towers that would not be in close proximity to existing access roads would utilize micropile foundations. For each tower leg, micropile foundations would use a group of three to eight 6- to 9-inch diameter casings that would be drilled and grouted into the ground. The exposed portion of the pile group would be encased in a reinforced concrete cap from the top of the casings to a depth anywhere from one to eight feet below the ground surface, depending on the terrain.

Conductor installation would proceed in the same manner as the double-circuit tower installation. The equipment necessary for conductor installation would be large, heavy construction equipment that could only be brought in by truck. Some NFS roads could need maintenance or improvement to allow pulling and tensioning, but no new access or spur roads would be created for conductor installation on the helicopter-constructed towers. After project completion, any maintained access roads to helicopter fly yards/staging areas to would be reduced to 16-feet.

1.2.2. Addition of New 230 kV Circuit

Between the proposed Haskell Canyon Switching Station and the existing Castaic Power Plant, LADWP proposes the addition of 12 miles of a new 230 kV transmission circuit onto existing Castaic – Olive 230 kV Transmission Line structures. The circuit would cross the unincorporated communities of Castaic and Saugus and the city of Santa Clarita. A total of 300 feet of BLM-managed public lands and four miles of NFS lands would be traversed; however, the new circuit would not require a new or additional ROW. This new circuit would be called Castaic – Haskell Canyon #4 and would utilize the same conductor (bundled 715.5 kcmil "Starling" ACSS/AW [aluminum conductor steel supported/aluminum-clad steel wire]) as that proposed for the new 230 kV transmission line between Barren Ridge and Haskell Canyon Switching Stations.

The addition of a new circuit on existing towers would require many of the same construction activities associated with a new transmission line (refer to Appendix C for a description of each construction activity). However, all work would be within existing ROW and no new towers would be constructed. Some towers may need to be modified or reinforced to carry the additional weight of the new conductor. Specific towers requiring reinforcement would be determined following detailed design of the Project. Tower reinforcement would not alter the general design or the location of the structures. This process would generally include reinforced foundations or steel member replacements. Refer to Figure 1-1 for a map showing the location of the new 230 kV circuit.

1.2.3. Reconductoring of Existing Transmission Line

LADWP proposes the reconductoring of 76 miles of the existing BR-RIN 230 kV transmission line with larger conductors from the Barren Ridge Switching Station to Rinaldi Substation. Four miles of BLM-managed public lands, 13 miles of National Forest System (NFS) lands, and 44 miles of private property would be traversed. The existing conductors (954/ 2,312 kcmil) would be replaced with a new 1,433.6 kcmil "Merrimack" ACSS/TW/HS (aluminum conductor steel supported/trapezoidal wires/high strength) conductor. The new conductor would have a larger diameter that allows for greater electrical capacity.

The upgrade of the existing BR-RIN would also require many of the same activities of the new transmission line (surveying of right-of-way [ROW], rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, and cleanup). Removal of the existing conductor would be used to string a pulling line, and this line would then be used to pull in the new conductor. All work would remain within the existing 250-foot-wide ROW, with no additional ROW required. Some of the towers would need to be modified, replaced, and/or have foundations reinforced or replaced to carry the additional weight of the new heavier conductor. Refer to Figure 1-1 for the location of the reconductoring.

1.2.4. Construction of New Switching Station

As a component of the BRRTP, LADWP proposes the construction of a new switching station in Haskell Canyon, south of the Angeles National Forest on LADWP-owned property at the convergence of several existing and proposed 230 kV transmission lines (the existing BR-RIN, the proposed double-circuit Barren Ridge – Haskell Canyon, existing Castaic – Northridge, Castaic – Sylmar, Castaic – Olive, and the proposed Castaic – Haskell Canyon). Refer to Figure 1-1 for the location of the new switching station.

The station would be approximately 500 feet by 600 feet to accommodate the necessary circuit positions, which are made up of equipment, such as steel support structures, circuit breakers, disconnect switches, and associated equipment, and a relay house and control house containing control and protective relaying equipment. The relay and control houses would each be approximately 30 feet long by 12 feet wide by 10 feet high and constructed of gray concrete block. The station yard would include a paved internal access road approximately 16 feet wide and would be enclosed by chain-link fencing with barbed-wire extension for security. The preliminary grading plan for the station is located in Appendix C.

Necessary pre-construction geotechnical investigation on-site would include six borings by a drill rig to investigate bedrock and soil stability and four cone penetration test locations after site grading to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

Construction of the new Haskell Canyon Switching Station would consist of preconstruction surveys, clearing and grading of access roads, site grading and drainage development, installation of concrete foundations and steel support structures, installation of below- and above-ground electrical conduits for equipment power and control, installation of below- and above-grade grounding conductors, and installation of control and relay houses. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks, and flatbed trailers. Cranes, man-lifts, portable welding units, line trucks, and mechanic trucks would also be required. Construction would require an estimated 12 months with approximately 60 workers.

Site preparation work for the station would involve clearing and grading of access roads, clearing of the switchyard site, the cut and fill grading of the site, and placement and compaction of structural fill that would serve as a base for switching station facilities. The site would be graded to maintain current drainage patterns as much as possible. A 16-foot-wide paved road and a 100-foot by 100-foot gravel parking area would be required. The yard would be covered with crushed-rock aggregate. Native vegetation would be re-established where possible outside the switchyard fence.

Following site grading and development, reinforced concrete foundations would be installed to support the steel structures and electrical equipment and control facilities. It is estimated that 1,500 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 180 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 120-day working period. Subsequent to the foundation installation, trenches would be dug to facilitate placement of copper conductors for the station grounding mat.

Multiple transmission lines would be terminated into the switching station (i.e., the new and existing Barren Ridge – Haskell and Castaic – Haskell Canyon transmission lines) and would need support and require the installation of galvanized steel structures. An existing 115 kV transmission line may need to be relocated around the proposed station. High-voltage bus work consisting of aluminum jumpers and tubing would be installed within the station.

1.2.5. Expansion of Existing Switching Station

LADWP proposes expansion of the existing Barren Ridge Switching Station to the east side by 235 feet by 500 feet, for a total station size of 485 feet by 500 feet (approximately 5.6 acres). The expansion area of the station would include electrical structures and equipment for the addition of transmission lines, a material staging area, roadway within the station, and a drainage area. The preliminary design layout for the station may be found in Appendix C. Refer to Figure 1-1 for the location of the existing switching station.

Expansion of the existing switching station would be very similar to the construction of the Haskell Canyon Switching Station as described above. Expansion would consist of preconstruction surveys, site preparation and grading, installation of reinforced concrete foundations, installation of electrical conduits for equipment power and control, and installation of structures and equipment.

Necessary pre-construction geotechnical on-site investigation would include two test pits excavated by a backhoe to investigate soil density and settlement, and four cone penetration test locations on-site to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

It is estimated that 700 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 80 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 90-day working period. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks, and flatbed trailers. Cranes, man-lifts, portable-welding units, line trucks, and mechanic trucks would also be required. An estimated eight months with approximately 60 workers would be required to expand the station.

1.2.6. Project-Wide Mitigation Measures

To address potential impacts of the Proposed Project to multiple resource areas as discussed above, the following project-wide mitigation measure would be applied:

> Three-Circuit Tower Mitigation (THREE-CIRCUIT) – A three-circuit lattice tower design would be implemented as described in Section 1.2.1 of this Technical Report, at the locations shown in Figure 1-7, Three-Circuit Tower Mitigation Map.
>
> Helicopter Mitigation (HELICOPTER) – Helicopter Mitigation shall be implemented, as described in Section 1.2.1 of this Technical Report, in steep areas of the Angeles National Forest where access is limited. For Alternatives 1 and 2a, implementation would occur at the locations shown on Figure 8-2, Identified Helicopter Mitigation Map. During final design of the Project, areas other than those shown on Figure 8-2, including Alternatives 2 and 3, may potentially require helicopter construction of the towers. This determination would generally be made where tower sites have no existing access roads within 300 feet and slopes are greater than 25 percent. Final identification of these tower sites would be determined and agreed upon by USFS, BLM and LADWP.

1.2.7. Construction Work Force and Schedule

The NEPA Record of Decision and CEQA Notice of Determination (anticipated in the early part of 2012) must be made before construction could begin. Therefore, construction of the BRRTP is anticipated to begin no sooner than summer 2012, with a target in-service date of early 2015. These dates are subject to change based on actual completion of design.

The following construction estimates were based on preliminary engineering and the number of workers and construction duration values are estimates; therefore, they are subject to change based on final engineering and design. The new double-circuit 230 kV transmission line from the Barren Ridge Switching Station to the proposed Haskell Canyon Switching Station would require 12.5 months and 134 workers. The installation of a 230 kV circuit on existing double-circuit towers from the Castaic Power Plant to the proposed Haskell Canyon Switching Station would require a month and a half and 35 workers. The upgrade and reconductoring of the existing BR-RIN would require eight months and 155 workers. The construction of a new 400-foot by 600-foot Haskell Canyon Switching Station would require 12 months and 60 workers. The expansion of the existing Barren Ridge Switching Station would require eight months and 60 workers.

The BRRTP components are anticipated to be constructed in the staggered sequence illustrated below in Tables 1-1 and 1-2. The construction of all Project components would take approximately two years and 447 total workers, with 173 workers at the peak of construction. Table 1-2 summarizes the BRRTP's anticipated construction workforce and schedule based on the most current information available. To allow for any delays in the Project, three weeks of float time were included for the new 230 kV transmission line and reconductoring efforts, and an additional two weeks of float time were included for the stringing of the second circuit between Castaic Power Plant and Haskell Canyon.

TABLE 1-1. ANTICIPATED CONSTRUCTION SEQUENCE

PROJECT COMPONENT	ANTICIPATED CONSTRUCTION SEQUENCE
Expansion of Barren Ridge Switching Station	Weeks 8 – 73
New Haskell Canyon Switching Station	Weeks 1 – 67
New 230 kV Transmission Line	Weeks 42 – 113
Reconductor BR-RIN	Weeks 55 – 88
Addition of 230 kV Circuit	Weeks 51 – 56

TABLE 1-2. CONSTRUCTION WORKFORCE AND SCHEDULE

PROJECT COMPONENT	CONSTRUCTION (START AND END WEEKS)	CONSTRUCTION DURATION (MONTHS)	TOTAL # OF WORKERS	PEAK # OF WORKERS AT ANY GIVEN TIME
Expansion of Barren Ridge Switching Station	8 – 73	15	60	38
New Haskell Canyon Switching Station	1 – 67	15.4	63	38
New 230 kV Transmission Line	42 – 113	16.5	134	131
Reconductor BR-RIN	55 -88	9	155	120
Addition of 230 kV Circuit	51 – 56	1.5	35	35
ALL COMPONENTS	**Weeks 1 – 113**	**26.1 months**	**447 Total Workers**	**173* Peak Workers**

*The value represents the total for the staggered construction of the Project components; it is not reflective of the sum of all the components.

2.0 REGULATORY FRAMEWORK

This Project must comply with various federal, state, and local laws. The following is a list of laws and policies relevant to water resources.

2.1 FEDERAL

Section 404 Clean Water Act. Waters of the U.S. including wetlands are subject to U. S. Army Corps of Engineers (USACE) jurisdiction under Section 404 of the Clean Water Act (CWA). A Section 404 permit is required for the discharge of dredged or fill material into Waters of the U.S. The Los Angeles District of the USACE would provide review and permitting services for this Project.

Section 401 Clean Water Act. Pursuant to Section 401 of the CWA, a water quality certification is required from the California State Water Resources Control Board (SWRCB) for Section 404 permit activities in multiple Regions. The SWRCB certifies that the discharge complies with state water quality standards and ensures that there is no net loss of wetlands through impact avoidance, minimization, and mitigation.

Section 303(d) Clean Water Act. Section 303(d) unites the water quality management strategies of the CWA. Section 303(d) requires that states make a list of waters that exceed the minimum level of pollutants put in place by the CWA. For waters on this list the states must develop total maximum daily loads (TMDLs) which account for all sources of the pollutants that caused the water to be listed. The TMDLs must account for contributions from both point sources and nonpoint sources, as defined by Section 402 of the CWA. In California, the State Water Resources Control Board (SWRCB) has interpreted state law (see Porter-Cologne Water Quality Control Act below) to require that implementation of TMDLs be addressed when incorporated into Basin Plans (water quality control plans).

Angeles National Forest Land Management Plan. The United States Forest Service (USFS) developed a Land Management Plan (USFS 2005) for the Angeles National Forest (Forest), which provides management direction for activities within the Forest. The Plan includes a description of Program Strategies and Tactics geared toward achieving the desired goals of the Plan. Strategies associated with water resources include Watershed Function, Water Management, and Hazardous Materials.

Bureau of Land Management West Mojave Plan. The Bureau of Land Management (BLM, California Desert District, developed a Habitat Conservation Plan and California Desert Conservation Area Plan Amendment for the West Mojave Desert area (BLM 2005). The West Mojave Plan is a habitat conservation plan and federal land use plan amendment that presents a comprehensive strategy to conserve and protect over 100 sensitive plants, animals, and the natural communities of which they are a part, and provides a streamlined program for complying with the California and Federal Endangered Species Acts.

Wild and Scenic Rivers Act. The National Wild and Scenic Rivers System was created by Congress in 1968 (Public Law 90-542; 16 U.S.C. 1271 *et seq.*) to preserve certain rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The Act is notable for safeguarding the special character of these rivers, while also recognizing the potential for their appropriate use and development. Designated segments need not include the entire river, and may include tributaries.

2.2 STATE

Porter-Cologne Water Quality Control Act. The Porter-Cologne Water Quality Control Act defines "water quality objectives" as the allowable "limits or levels of water quality constituents or characteristics which are established for the reasonable protection of beneficial uses of water or the prevention of nuisance within a specific area." Thus, water quality objectives are intended to protect the public health and welfare, and to maintain or enhance water quality in relation to the existing and/or potential beneficial uses of the water. Water quality objectives apply to both Waters of the United States and Waters of the State.

Basin Plans. The SWRCB requires individual Regional Water Quality Control Boards (RWQCBs) to develop Basin Plans (water quality control plans) designed to preserve and enhance water quality and protect the beneficial uses of all Regional waters. Specifically, Basin Plans designate beneficial uses for surface waters and groundwater, set narrative and numerical objectives that must be attainted or maintained to protect the designated beneficial uses and conform to the States antidegradation policy, and describe implementation programs to protect all waters in the Regions. In addition, Basin Plans incorporate by reference all applicable State and Regional Board plans and policies, and other pertinent water quality policies and regulations. The BRRTP is under the jurisdiction of the Basin Plans of the Los Angeles Regional Water Quality Control Board and the Lahontan Regional Water Quality Control Board.

Construction Storm Water Program. The SWRCB and the nine RWQCBs implement water quality regulations under the federal CWA and California Porter Cologne Water Quality Control Act. Existing water quality regulations require compliance with the National Pollutant Discharge Elimination System (NPDES) for discharges of storm water runoff associated with a construction activity.

Dischargers whose projects disturb one or more acres of soil are required to obtain coverage under the General Permit for Discharges of Storm Water Associated with Construction Activity (Construction General Permit, 2009-2009-DWQ). Construction activity subject to this permit includes clearing, grading, and disturbances to the ground such as stockpiling or excavation, but does not include regular maintenance activities performed to restore the original line, grade, or capacity of the facility.

The Construction General Permit requires the development and implementation of a Storm Water Pollution Prevention Plan (SWPPP). The SWPPP should contain a site map(s) which shows the construction site perimeter, existing and proposed buildings, lots, roadways, storm water collection and discharge points, general topography both before and after construction, and drainage patterns across the Project. The SWPPP must list Best Management Practices (BMPs) the discharger will use to protect storm water runoff and the placement of those BMPs. Additionally, the SWPPP must contain a visual monitoring program, a chemical monitoring program for “non-visible” pollutants to be implemented if there is a failure of BMPs, and a sediment monitoring plan if the site discharges directly to a water body listed on the 303(d) list for sediment.

If a single project traverses more than one RWQCB jurisdiction, a complete Notice of Intent Package and Notice of Termination must be filed with each jurisdiction. The BRRTP crosses the jurisdictions of the Los Angeles Regional Water Quality Control Board (Region 4) and the Lahontan Regional Water Quality Control Board (Region 6).

Lake or Streambed Alteration Agreement. Section 1602 of the California Department of Fish and Game (CDFG) Code protect the natural flow, bed, channel, and bank of any river, stream, or lake designated by the CDFG, in which there is at any time an existing fish or wildlife resource, or from which these resources derive benefit. General project plans must be submitted to CDFG in sufficient detail to indicate the nature of a project for construction, if the project would:

- Divert, obstruct, or change a streambed
- Use material from the streambeds
- Result in the disposal or deposition of debris, waste, or other material containing crumbled, flaked, or ground pavement where it can pass into a stream

The Central Region of the CDFG serves Kern County, and the South Coast Region of the CDFG serves Los Angeles County.

2.3 LOCAL

The Los Angeles County Draft General Plan sets forth goals and policy direction for the management of the County's water resources (County of Los Angeles 1980).

Conservation and Open Space Element

Policy Statement: Conserve Water Supply and Protect Water Quality.

> Policy 4: Protect ground water recharge and watershed areas, conserve storm and reclaimed water, and promote water conservation programs.
> Policy 5: Encourage the maintenance, management, and improvement of the quality of imported domestic water, ground water supplies, natural runoff and ocean water.

Policy Statement: Conserve Natural Areas.

> Policy 12: Protect watershed, streams, and riparian vegetation to minimize water pollution, soil erosion and sedimentation, maintain natural habitats, and aid in ground water recharge.

The Kern County General Plan presents policies and goals regarding the growth and resources of unincorporated Kern County (Kern County 2007).

Land Use, Open Space, and Conservation Element

Policies: Physical and Environmental Constraints

> Policy 8: Encourage the preservation of the floodplain's flow conveyance capacity, especially in floodways, to be open space/passive recreation areas throughout the County.
>
> Policy 9: Construction of structures that impede water flow in a primary floodplain will be discouraged.
>
> Policy 10: The County will allow lands which are within flood hazard areas, other than primary floodplains, to be developed in accordance with the General Plan and Floodplain Management Ordinance, if mitigation measures are incorporated so as to ensure that the proposed development will not be hazardous within the requirements of the Safety Element of this General Plan.
>
> Policy 11: Protect and maintain watershed integrity within Kern County.

Implementation Measures: Physical and Environmental Constraints

> Measure H: Development within areas subject to flooding, as defined by the appropriate agency, will require necessary flood evaluations and studies.
>
> Measure I: Designated flood channels and water courses, such as creeks, gullies, and riverbeds, will be preserved as resource management areas or in the case of urban areas, as linear parks whenever practical.
>
> Measure J: Compliance with the Floodplain Management Ordinance prior to grading or improvement of land for development or construction, expansion, conversion, or substantial improvements of a structure is required.

Policies: Resource

> Policy 11: Minimize the alteration of natural drainage areas. Require development plans to include necessary mitigation to stabilize runoff and silt deposition through utilization of grading and flood protection ordinances.
>
> Policy 20: Areas along rivers and streams will be conserved where feasible to enhance drainage, flood control, recreational, and other beneficial uses while acknowledging existing land use patterns.

Implementation Measure: Resource

> Measure E: Designate the riparian community abutting rivers and streams with an appropriate resource use or resource management designation when feasible to do so.

3.0 PROJECT AREA OVERVIEW

The northern half of the BRRTP is located within the Antelope Valley Watershed (Antelope Hydrologic Unit Code 18090206) in Kern and Los Angeles Counties, California. The Antelope Valley Watershed drains 3,387 square miles, mainly from streams originating in the mountains and foothills surrounding the valley. Due to the relatively flat topography of the Antelope Valley, there are few defined natural stream channels within the valley floor; thus, the valley floor is subject to unpredictable sheet flow patterns.

The climate of the Antelope Valley is arid. Due to orographic lifting and precipitation (rain shadow effect), in which mountains to the west and south block most storms and resulting precipitation from passing to the leeward side of the mountain range, most storms in the Antelope Valley are the result of convective storms, which can result in serious flash flooding (Glenn Harris, personal communication). Precipitation extremes are common: variations of 80 percent in annual precipitation can occur. A summer thunderstorm can generate more precipitation on one site than the annual mean for that location (BLM 2005). Annual precipitation in the Antelope Valley ranges from between 15.81 inches in Fairmont to 5.87 inches in the unincorporated community of Mojave, with 23 percent to 41 percent falling as snow (Western Regional Climate Center 2008). High winds can also occur; peak wind velocities of 50 miles per hour are not uncommon, and winds with velocities of 100 miles per hour occur every year (BLM 2005).

The southern half of the study area is within the Santa Clara River Watershed (Santa Clara-Calleguas Hydrologic Unit Code 18070102), and Los Angeles River Watershed (Los Angeles Hydrologic Unit Code 18070105). The Santa Clara River and its watershed drain an area of approximately 1,634 square miles, from the river's headwaters at Pacifico Mountain in the San Gabriel Mountains southwest to its mouth at the Pacific Ocean, just south of the City of Ventura, in Ventura County, California. The Los Angeles River Watershed drains approximately 830 square miles, and the Los Angeles River receives water from tributaries in the San Gabriel Mountains, Santa Monica Mountains, and the Santa Susana Mountains, and groundwater seeps but, south of San Fernando Valley, flows are dominated by urban runoff and flood flows, and effluent from several municipal wastewater treatment plants (Los Angeles RWQCB 1994).

The climate of the southern half of the BRRTP area is Mediterranean, with warm, dry summers and cool, wet winters. Most precipitation occurs between November and March, when storm systems from the north Pacific approach the area from the west or southwest, often producing precipitation simultaneously throughout the area. The orographic effect often results in intense precipitation along and within the San Gabriel Mountains. Annual precipitation in the higher elevations averages 14.32 inches at Elizabeth Lake, with over 95 percent falling as snow. In San Fernando, in the lower elevations, annual precipitation averages 17.66 inches, with less than one percent falling as snow (Western Regional Climate Center 2008).

Both portions of the study area include areas of urban and suburban development. In the last four decades, increased agricultural growth in the northern half of the study area and rapid population growth in the Antelope Valley, Santa Clarita Valley, and San Fernando Valley have resulted in changes in surface water flow and increased water demand.

4.0 INVENTORY METHODS

The goal of the water resource inventory was to identify, map, describe, and document existing water resources within the study corridors of each segment. Detailed data inventories were compiled to facilitate the assessment of potential water resource impacts resulting from construction and operation of the Project.

Initially, base maps of the Project area were prepared at a scale of 1:12,000. Water resource data collected from federal and state databases were reviewed, refined, and updated. Existing maps from the United States Geological Survey (USGS), National Wetland Inventory (NWI), and Federal Emergency Management Agency (FEMA) were collected and included in the inventory, as appropriate. These data were compiled and mapped utilizing a geographic information system (GIS).

The study used National Agriculture Imagery Program (NAIP) 2005 color aerial photography, and national, state, and local agency GIS data layers to identify and more accurately assess surface land uses and land cover types.

A description of water resources was divided by segment. Existing water resources were identified within the segment study corridor in order to present an overview of the water resources near the transmission line alternatives.

5.0 AFFECTED ENVIRONMENT

The water resources study was divided into nine categories to facilitate the inventory and analysis of water resources within the study area:

- watersheds
- floodplains
- surface water
- lakes and reservoirs
- hydric soils
- wetlands
- Riparian Conservation Areas and Significant Ecological Areas
- Groundwater and wells
- water quality

5.1 WATERSHEDS

A watershed is the geographic area draining into a river system, ocean, or other body of water through a single outlet, and includes the receiving waters of that system. Watersheds are usually bordered and separated from other watersheds by mountain ridges or other naturally elevated areas (Los Angeles RWQCB 2007), and contain multiple sub-watersheds. The BRRTP study area traverses three watersheds: Antelope Valley Watershed, Santa Clara River Watershed, and the Los Angeles River Watershed.

5.1.1. Antelope Valley Watershed

(Antelope Hydrologic Unit Number 18090206)

The Antelope Valley Watershed is a large, closed basin in the western Mojave Desert, with a drainage area of 3,387 square miles. Surface water drains into the watershed by way of tributaries in the San Gabriel Mountains, the Tehachapi Mountains, and from precipitation. With no outlet to the ocean, surface water flowing into Antelope Valley either infiltrates into the groundwater basin, flows toward three playas located east of the study area (in Edwards Air Force Base), or is lost through evapotranspiration. Due to the aridness of the climate, more surface water is lost to evapotranspiration than either infiltrates to groundwater storage or discharges to the existing playas in the Antelope Valley (Los Angeles County Sanitation District (LACSD 2004, 2006).

5.1.2. Santa Clara River Watershed

(Santa Clara-Calleguas Hydrologic Unit Code 18070102)

The Santa Clara River Watershed drains approximately 1,634 square miles. The Santa Clara River has its headwaters at Pacifico Mountain in the San Gabriel Mountains, and flows southwest to drain in the Pacific Ocean between the Cities of San Buenaventura and Oxnard, California. The river is divided into two sections: the Upper Santa Clara River, comprised of the main course of the river upstream of the Los Angeles – Ventura County line, and the Lower Santa Clara River. The BRRTP study area is within the Santa Clara Watershed in the vicinity of the Upper Santa Clara River. Major tributaries in the study area include Castaic Creek and San Francisquito Creek (VCWPD AND LACDPW 2005).

5.1.3. Los Angeles River Watershed

(Los Angeles Hydrologic Unit Code 18070105)

The Los Angeles River Watershed drains approximately 830 square miles. The Los Angeles River receives flow from tributaries in the San Gabriel Mountains, the Santa Monica Mountains, and the Santa Susana Mountains, and groundwater seeps in the Glendale Narrows, but south of San Fernando Valley flows are dominated by urban runoff and flood flows, and effluent from several municipal wastewater treatment plants (Los Angeles RWQCB 1994). South of the Glendale Narrows, the river is channelized to Willow Street in the City of Long Beach, California, where it reverts to a soft bottom. The Los Angeles River drains into the Pacific Ocean approximately 2.75 miles south of Willow Street, in the City of Long Beach (Los Angeles RWQCB 2007).

5.2 FLOODPLAINS

A floodplain is a relatively flat geographical area (e.g., a valley floor) adjacent to and formed by alluvial streams and rivers that are occasionally subject to inundation. Functioning floodplains provide flood management, acting as temporary storage of flood water. This storage of water decreases run-off velocity, reduces flood peaks, and distributes storm flows over longer time periods, causing tributary and main channels to peak at different times. Floodplains can also provide important and rich habitats as a result of the associated alluvial and riparian ecosystems.

A 100-year floodplain is an area of land that has a one percent chance of inundation every year, or once every 100 years. The Federal Emergency Management Agency (FEMA) has estimated and mapped 100-year floodplains in the Antelope Valley, Santa Clara River, and Los Angeles River Watersheds. FEMA has categorized 100-year floodplains as Flood Hazard Areas, and requires construction activities within these areas to comply with floodplain management ordinances.

Within the BRRTP study area, large 100-year floodplains have been identified in the Antelope Valley (see Figure 5-1). The largest mapped floodplain lies between the mouths of Oak Creek and Cottonwood Creek, south of the Tehachapi Mountains, and stretches south beyond the Kern – Los Angeles County line. A second large floodplain occurs near the junctions of Segments A, B, and C, along the southern slopes of the Tehachapi Mountains.

The majority of the mapped 100-year floodplains occurring within or along the study corridors are smaller than those of the Antelope Valley, and tend to be confined to the canyons of their associated waterways. Smaller 100-year floodplains have been identified along the San Andreas Fault, within San Francisquito Canyon, Bouquet Canyon, Mint Canyon, and Soledad Canyon along the Santa Clara River, along the Santa Clara River, and south of the City of Santa Clarita.

5.3 SURFACE WATER

Due to the arid climate of the northern half of the study area and the Mediterranean climate of the southern half, many of the streams are ephemeral in nature. An ephemeral stream is a stream or reach of channel that flows only in direct response to precipitation in the immediate locality, and whose channel is above the zone of saturation (Briggs 1996). Sheet flow will occur in many areas during periods of heavy rainfall (LACSD 2004).

An intermittent stream is a stream or reach of a channel that flows only during certain times of year; for example, when it receives water from a spring, seep, melting snowpack from the higher elevations, or other periodic source (Briggs 1996). The southern half of the study area contains numerous intermittent streams.

A perennial stream or river is a stream, river, or reach of channel that flows more or less continuously throughout the year, and whose upper surface is generally below the upper zone of saturation (Briggs 1996). With the exception of very wet years, water in many perennial streams in the study area percolates into the streambed, recharging groundwater basins. As a result, the stream channels of most perennial streams are dry during the summer. The Santa Clara River has natural perennial flow west of the Project area, from approximately Interstate 5 west beyond the Los Angeles – Ventura County line. More recently, perennial flow has been extended upstream toward Bouquet Canyon due to reclaimed water discharges from the Saugus Water Reclamation Plant (LACSD 2009).

THIS PAGE INTENTIONALLY LEFT BLANK

Water has been imported into the Los Angeles area since 1913, when the Los Angeles Aqueduct began delivering water from the Owens Valley. Since that time, southern California has developed a complex system of aqueducts to import water to support a rapidly growing population and economy. Aqueducts cross through the study area as they transport water from northern and central California into southern California.

The Los Angeles Aqueducts, operated by LADWP, divert water from the Mono and Owens River Basins and transport this water 338 miles to the City of Los Angeles. The original aqueduct was completed in 1913, and a second aqueduct, generally paralleling the first, was completed in 1970.

The California Aqueduct, operated by the California Department of Water Resources (DWR), transports water from northern California to southern California, where the aqueduct branches into two aqueducts; one branch terminates at the Perris Reservoir in the City of Perris, in the County of Riverside, while the other branch terminates at the Castaic Reservoir, in the southern half of the study area.

The BRRTP crosses three major watersheds: the Antelope Valley Watershed, the Santa Clara River Watershed, and the Los Angeles River Watershed. The northern portion of the Project occurs entirely within the Antelope Valley Watershed, which is a closed basin into which flow perennial and intermittent streams from the Tehachapi Mountains and the San Gabriel Mountains.

Within the Antelope Valley Watershed, streams crossed by the study corridors include Cache Creek, Oak Creek, Cottonwood Creek, Amargosa Creek, Anaverde Creek, Railroad Canyon Creek, Willow Springs, and multiple unnamed perennial and intermittent streams.

The southern portion of the Project occurs within the Santa Clara River Watershed, with a small section crossing into the Los Angeles River Watershed. The Santa Clara River is the largest river system in southern California that remains in a relatively natural state. Principle tributaries of the upper Santa Clara River include Bouquet Canyon Creek and San Francisquito Canyon Creek, both of which are crossed by the study corridors. San Francisquito Canyon Creek is an eligible Wild and Scenic River.

Also crossed by study corridors are South Portal Canyon Creek, Cherry Canyon Creek, Bee Canyon Creek, Baird Canyon Creek, Dry Canyon Creek (perennial and intermittent portions), Martindale Canyon Creek, Pettinger Canyon Creek, Vasquez Canyon Creek, Charlie Canyon Creek, Bitter Canyon Creek, Soledad Canyon Creek, Oro Fino Canyon Creek, Quigley Canyon Creek, Placerita Canyon Creek, Whitney Canyon Creek, Elsmere Canyon Creek, Liebre Gulch, West Fork Liebre Gulch, and numerous unnamed perennial and intermittent streams.

The southernmost portion of Segment K crosses into the Los Angeles River Watershed. This study corridor crosses Grapevine Canyon Creek and one unnamed stream, both of which are intermittent.

Segment C parallels the First and Second Los Angeles Aqueducts in the northernmost portion of the Project, and both aqueducts occur within the study corridor. The Los Angeles Aqueduct is crossed by Segments G and K, in the southern portion of the Project.

The California Aqueduct is crossed by Segment D near 270th Street West at mile point 13.6. Segments G, H, and I cross the California Aqueduct where the aqueduct parallels the northern slopes of Portal Ridge.

5.4 LAKES AND RESERVOIRS

The majority of water bodies in the Project area are reservoirs operated by either the California State Water Project or LADWP, as part of the Los Angeles Aqueduct system. Dry lakes, or playas, occur in the arid northern portion of the Project area, and natural lakes occur along the San Andreas Rift Zone.

Four natural lakes occur in the study area: Elizabeth Lake, Lake Hughes, Munz Lake and Quail Lake. All four lakes are rift lakes located in the San Andreas Rift Zone. Rift lakes are formed in depressions created where active or recent strike/slip faults movement has impounded drainage.

Elizabeth Lake and Lake Hughes are located approximately one mile west and four miles west of the Segment G study corridor, respectively. Existing beneficial uses of Elizabeth Lake and Lake Hughes are warm freshwater and wildlife habitats, and both contact and non-contact water recreation. In addition, Elizabeth Lake is classified as supporting habitats necessary, at least in part, for the survival and successful maintenance of plant or animal species established under state or federal law as rare, threatened, or endangered. Potential beneficial uses of Elizabeth Lake and Lake Hughes are municipal and domestic water supply, industrial process and service supply, agricultural supply, groundwater recharge, and freshwater replenishment (Los Angeles RWQCB 1994).

Munz Lake is situated between Elizabeth Lake and Lake Hughes. Existing beneficial uses for Munz Lake are contact and non-contact water recreation, groundwater recharge, and warm freshwater and wildlife habitats. Potential beneficial uses are municipal and domestic water supply, industrial process and service supply, agricultural supply, and freshwater replenishment (Los Angeles RWQCB 1994).

Quail Lake is located north of Segment D, near the junction of Highway 138 and the Old Ridge Route. Quail Lake was enlarged by DWR as part of the California Water Project to ensure safe water passage across the San Andreas Rift Zone. As part of the California Aqueduct system, Quail Lake provides regulatory storage for water transported via the West Branch California Aqueduct. Water is pumped into the Lake from the West Branch California Aqueduct through the Oso Pumping Plant. At the western end of the lake, water enters a pipeline leading to Warne Power Plant, and is discharged into Pyramid Lake.

Five reservoirs occur within the study area. Bouquet Reservoir is located in Bouquet Canyon, adjacent to Segment H. Bouquet Reservoir is part of the Los Angeles Aqueduct System, and provides storage for water transported to the Los Angeles area from the Owens Valley. Existing beneficial uses of Bouquet Reservoir are municipal and domestic water supply, industrial process and service supply, agricultural water supply, groundwater recharge, freshwater replenishment, wildlife habitat, warm freshwater habitat, and non-contact water recreation. Potential beneficial uses are hydropower generation and contact water recreation.

Dry Canyon Reservoir was intended by LADWP to provide storage and flow regulation for the First Los Angeles Aqueduct; however, the reservoir was taken out of service in 1966 due to seepage problems. Currently, the reservoir stores water resulting from storm events only. Existing beneficial uses of the reservoir are municipal and domestic water supply, industrial process and service supply, agricultural water supply, non-contact water recreation, wildlife habitat, and warm freshwater habitat. Potential beneficial uses are groundwater recharge, freshwater replenishment, hydropower generation, and contact water recreation.

Castaic Lake is a reservoir that is part of the California State Water Project. The reservoir is the terminus of the west branch of the California Aqueduct. Water is released from Castaic Lake into Castaic Lagoon, immediately downstream of the reservoir. Existing beneficial uses for both Castaic Lake and Castaic Lagoon are municipal and domestic water supply, industrial process and service supply, agricultural water supply, groundwater recharge, contact and non-contact water recreation, wildlife habitat, and warm freshwater habitat. In addition, Castaic Lake is used for hydropower generation, habitat for rare, threatened, or endangered species, and spawning, reproduction, and/or early development habitat for fish species.

Pyramid Lake is located west of Segment D near milepost 29, on the border of the Angeles and Los Padres National Forests. Pyramid Lake is operated by the DWR as part of the California Aqueduct system, receiving water from the West Branch California Aqueduct via Quail Lake. The reservoir stores water for delivery to southern California, provides regulated storage for the Castaic Power Plant on Castaic Lake, and also provides flood protection for Piru Creek. Existing beneficial uses for Pyramid Lake are municipal and domestic water supply, industrial service water supply, industrial process water supply, agricultural supply, groundwater recharge, hydropower generation, contact and non-contact water recreation, warm and cold freshwater habitat, wildlife habitat, and rare, threatened, or endangered species habitat.

The Van Norman – Los Angeles Reservoir Complex consists of the Lower Van Norman Reservoir and the Los Angeles Reservoir. The Van Norman Reservoir was built by LADWP in 1916-1918, but sustained damage during the Sylmar Earthquake that occurred on February 9, 1971 and was replaced by the Los Angeles Reservoir. The Lower Van Norman Reservoir (also called Van Norman Lake) is what remains of the original reservoir. Los Angeles Reservoir, which replaced Van Norman Reservoir, is immediately north of the Lower Van Norman Reservoir. Existing beneficial uses of Lower Van Norman Reservoir are municipal and domestic water supply, industrial service and process supply, groundwater recharge, and wildlife habitat. Existing beneficial uses for the Los Angeles Reservoir are municipal and domestic water supply, industrial service and process supply, groundwater recharge, non-contact water recreation, wildlife habitat, warm freshwater habitat, and habitat for rare, threatened, or endangered species. Contact water recreation is a potential beneficial use of the Los Angeles Reservoir; however, public access to the reservoir complex is restricted by LADWP (Los Angeles RWQCB 1994).

While these lakes and reservoirs occur within the study area, only one occurs within or is crossed by a study corridor. Castaic Lagoon is crossed by Segment J just below the dam.

5.5 HYDRIC SOILS

Hydric soils are soils that are saturated at or near the surface, whether by flooding or high groundwater tables, of a frequency or duration that promotes the development of anaerobic conditions that affect plant growth and promote the establishment of hydrophytic vegetation. Some hydric soils have phases that are not hydric, depending on groundwater table, flooding, and ponding characteristics. Hydric soils were used in combination with land cover types to identify wetlands not mapped by NWI.

Digital soils data for the Soil Survey Geographic (SSURGO) were obtained from the Natural Resources Conservation Service (NRCS) for all quadrangles in the study area. SSURGO data are classified as follows: all hydric soils, partially hydric soils, not hydric soils, and no data available.

SSURGO data revealed one known occurrence of hydric soils. This location is west of Soledad Mountain along Mojave Tropico Road, and is approximately 1.5 miles east of the study corridor (Segment B). The data revealed many occurrences of partially hydric soils throughout the study area. In the northern portion, partially hydric soils are widespread throughout the floor of the Antelope Valley; along Segment D and within the southern portion in general, partially hydric soils are found primarily within canyons and along drainages.

5.6 WETLANDS

The regulatory definition of Section 404 CWA jurisdictional wetlands, according to the U.S. Environmental Protection Agency (EPA) and the USACE are "those areas that are inundated or saturated by surface or groundwater at a frequency or duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions."

Digital and hard copy NWI maps were obtained from the U.S. Fish and Wildlife Service (USFWS) for all quadrangles. Hard copy maps were digitized by POWER. NWI provides approximate locations of wetlands one acre or larger and may or may not be jurisdictional based on the 1987 USACE Wetlands Delineation Manual.

Data provided by the NWI revealed three types of wetlands occurring within the study corridors.

Palustrine Emergent Saturated wetlands (PEMB) are characterized by erect, rooted, herbaceous vegetation, present throughout most of the growing season except in the driest years. PEMB wetlands are saturated to the surface for extended periods during the growing season, but surface water is seldom present. There are four occurrences of PEMB wetlands within the study corridors. In Segment G, two PEMB wetlands occur approximately 0.3 mile south of Johnson Road between mile 5.4 and 5.6; within Segment H, two PEMB wetlands occur south of the intersection of Kellogg Valley Road and Power Line Road between mile 3.7 and 3.8, and two PEMB wetlands occur approximately 0.2 mile south of Elizabeth Lake Road between mile 4.4 and 4.5.

Palustrine Forested Temporarily Flooded wetlands (PFOA) are characterized by woody vegetation 20 feet tall or higher. Surface water in PFOA wetlands is present for brief periods during the growing season, but the water table usually lies well below the soil surface. One PFOA wetland occurs within the study corridors. This wetland is within the Segment H study corridor between mile 8.0 and 8.1, east of Bouquet Reservoir where Spunky Canyon Road meets Bouquet Canyon Road.

Palustrine Unconsolidated Bottom Permanently Flooded, Excavated basins (PUBFx) are artificially excavated basins characterized by open water habitat with erect, rooted, vegetative cover of less than 30 percent. Vegetation is usually found in shallow waters around the edges of the basin. PUBF basins are flooded throughout the year in most years; if surface water is absent, water is usually present at or very near the soil surface. This basin occurs on private property approximately 0.4 mile east of Johnson Siphon, within Segment H between mile 2.1 and 2.2.

5.7 RIPARIAN CONSERVATION AREAS AND SIGNIFICANT ECOLOGICAL AREAS

Riparian Conservation Areas (RCAs) combine the ecologic concerns of riparian ecosystems with the hydrologic concerns of floodplains and streamside slopes. RCAs have been established within the Angeles National Forest to protect, maintain, or improve water quality, site productivity, channel stability, riparian vegetation, and riparian-dependent species and habitats.

Riparian Conservation Areas are associated with many streams within the ANF, including West Fork Liebre Gulch, Liebre Gulch, San Francisquito Canyon, Dry Canyon, Bee Canyon, Pettinger Canyon, Munz Canyon, Mint Canyon, and multiple unnamed streams.

Significant Ecological Areas (SEAs) are defined by the County of Los Angeles as "ecologically important or fragile land and water areas, valuable as plant and animal communities. These areas are classified as one or more of the following: 1) habitats for rare and endangered species of plants and animals; 2) restricted natural communities—ecological areas which are scarce on a regional basis; 3) habitat restricted in distribution in the county; 4) breeding or nesting grounds; 5) unusual biotic communities; 6) sites with critical wildlife and fish value; and 7) relatively undisturbed habitat."

The following SEAs are located within the Project area:

Santa Clara River SEA
San Andreas Rift Zone SEA
Cruzan Mesa Vernal Pools SEA
Joshua Tree Woodlands SEA

Mountain Conservancy SEA
San Francisquito Canyon SEA

For detailed information on RCAs and SEAs in the Project area, refer to the Biological Resources Technical Report.

5.8 GROUNDWATER AND WELLS

As precipitation and snowmelt flow into creeks, streams, and rivers, much of the water percolates into the ground. These alluvial groundwater basins cover nearly 40 percent of the State of California. Approximately 43 percent of Californians obtain drinking water from groundwater, through both municipal and privately owned wells. The BRRTP study corridors cross four groundwater basins and one sub-basin. These basins are described in California's Groundwater Bulletin 118 and summarized below.

Locations of wells were obtained from the USGS and DWR. Depth-to-water well measurements are used to monitor groundwater basin levels, to record trends in groundwater depth, and to monitor groundwater quality.

In the northern section of the Project, the study corridors cross the Fremont Valley Groundwater Basin and the Antelope Valley Groundwater Basin. In the southern section of the Project, the study corridors cross the Acton Valley Groundwater Basin, the Santa Clara River Valley East Sub-basin, and the San Fernando Valley Groundwater Basin. Current groundwater levels and general trends in groundwater levels are obtained through depth-to-water measurements conducted in USGS wells and wells operated by the State of California.

Two wells occur within the study corridors. The first well (California State ID #08N16W04N001S) is located within Segment D, at mile marker 11.2. The most recent measurement from this well dates from 1962, when the depth-to-water measurement was 226.2 feet; however, a well approximately 0.75 mile southeast near Holiday Lake had a depth-to-water measurement of 246.3 feet in March 2008.

The second well (California State ID #07N14W10P001S) is located within Segment F adjacent to Avenue I at mile post 1.2. The most recent measurements at this well date from 1963, when the depth-to-water measurement was 318.2 feet; however, a USGS well, approximately two miles east of this location, had a depth-to-groundwater measurement of 242.06 feet in March 2008 (USGS 2009).

5.8.1. Fremont Valley Groundwater Basin (Groundwater Basin Number 6-46)

The Fremont Valley Groundwater Basin drains a surface area of 335,000 acres (523 square miles). The basin underlies the Fremont Valley, and is bounded on the east by crystalline rocks of the Summit Range, Red Mountain, Lava Mountains, Rand Mountains, Castle Butte, Bissel Hills, and Rosamond Hills. The basin is bounded on the southwest by the Antelope Valley Groundwater Basin along a groundwater divide approximated by a line connecting the mouth of Oak Creek through Middle Butte to exposed basement rock near Gem Hill.

The primary water-bearing layer in this basin is Quaternary alluvium, which is thickest around the basin margins, with a depth of approximately 1,190 feet. The alluvium thins toward the center of the basin. Groundwater in the basin is generally unconfined, but restricted by the Garlock and El Paso fault zones and partially restricted by the Muroc fault zone.

Total storage capacity of the Fremont Valley Groundwater Basin is approximately 4,800,000 acre feet (af). Well measurements indicate that from 1957 to 1999 groundwater levels in the southwestern part of the basin declined approximately nine feet. In the vicinity of the study corridors that cross the Fremont

Valley Groundwater Basin, recent depth-to-water measurements in USGS wells ranged between 117.37 feet and 345.04 feet (DWR 2003) (Table 5-1).

5.8.2. Antelope Valley Groundwater Basin (Groundwater Basin Number 6-44)

The Antelope Valley Groundwater Basin drains a surface area of approximately 1,010,000 acres (1,580 square miles). The basin underlies an extensive alluvial valley in the western Mojave Desert, and is bounded on the northwest by the Garlock fault zone at the base of the Tehachapi Mountains, on the southwest by the San Andreas fault zone at the northern base of the San Gabriel Mountains, on the east by ridges, buttes, and low hills that form a surface and groundwater drainage divide, and on the north by the Fremont Groundwater Basin described above.

The primary aquifers in this basin are unconsolidated alluvial and lacustrine deposits from the Pleistocene and Holocene, forming an upper aquifer and a lower aquifer. The upper aquifer is the primary source of groundwater in the Antelope Valley, and is generally unconfined. The basin is comprised of three large sediment-filled structural sub-basins separated by extensively faulted, elevated bedrock. Numerous faults displace the water table and impede groundwater flow within the basin.

Total storage capacity of the Antelope Valley Groundwater Basin is between 68,000,000 and 70,000,000 af, except for an area of the basin where the groundwater is between 20 and 220 feet in depth. In that area, the storage capacity is approximately 5,400,000 af. Between 1975 and 1998, groundwater in this basin ranged from an increase of 84 feet to a decrease of 66 feet. The area of the basin that experienced a decrease in groundwater depth is along the State Route 14 corridor from Palmdale to Rosamond. In the vicinity of the study corridors that cross the Antelope Valley Groundwater Basin, recent depth-to-water measurements in USGS wells ranged between 152.83 feet and 390.79 feet (DWR 2003) (Table 5-1).

5.8.3. Acton Valley Groundwater Basin (Groundwater Basin Number 4-5)

The Acton Valley Groundwater Basin drains a surface area of approximately 8,270 acres (12.9 square miles). The basin is unconfined, and groundwater is found in alluvium and stream terrace deposits. The basin is bounded by the Sierra Pelona on the north, and the San Gabriel Mountains on the south, east, and west.

Groundwater in the basin is unconfined. The water-bearing formations in this basin are Holocene alluvial deposits and Pleistocene stream terrace deposits. The alluvial deposits reach a maximum thickness of approximately 225 feet in the Santa Clara River channel near the community of Acton, and thin out east and west of this area. The stream terrace deposits are found on low-lying flanks of the foothills and upper reaches of the tributaries of the Santa Clara River, and reach a maximum thickness of approximately 210 feet north of Acton.

Total storage capacity of the Acton Valley Groundwater Basin is approximately 40,000 af. Groundwater levels declined from the 1950s through the mid-1970s; groundwater levels increased from the late 1970s through the mid-1980s, but began declining again. Current depth-to-water measurements were unavailable for the Acton Valley Groundwater Basin (DWR 2003) (Table 5-1).

5.8.4. Santa Clara River Valley East Sub-basin (Groundwater Basin Number 4-4.07)

The Santa Clara River Valley East Sub-basin drains a surface area of approximately 66,200 acres (103 square miles). The basin is bounded on the north by the Piru Mountains, on the west by impervious rocks of the Modelo and Saugus Formations and a constriction in the alluvium, on the south by the Santa Susana Mountains and the San Gabriel Mountains, and on the east by the San Gabriel Mountains.

Groundwater in the sub-basin is found in Holocene alluvium, Pleistocene terrace deposits, and in the late Pliocene to early Pleistocene Saugus Formation. Groundwater is generally unconfined in the alluvium, but may be confined, semi-confined, or unconfined in the Saugus Formation. Alluvium deposits reach a maximum thickness of approximately 240 feet below the Santa Clara River channel and thin laterally away from the channel, and east and west of the community of Acton. The terrace deposits generally lie above the water table, and are found on the low-lying flanks of the foothills and upper reaches of the Santa Clara River tributaries. These deposits reach thicknesses of up to 200 feet near Saugus, Agua Dulce, and Acton. The Saugus Formation is up to 8,500 feet thick, and is not widely utilized as a groundwater source for municipal and agricultural uses as the water can be brackish. The maximum depth to the base of fresh water ranges from 1,500 feet northeast of the San Gabriel Fault to 5,500 feet between the San Gabriel Fault and the Holser Fault.

Although the Saugus Formation is displaced by both the San Gabriel and Holser Faults, groundwater movement in the Formation has not been affected. The water-bearing alluvial deposits have not been affected by fault displacement.

Total storage capacity of the sub-basin is approximately 240,000 af in the alluvial aquifer, and approximately 1,650 af in the Saugus Formation. Between 1970 and 2000, groundwater levels were relatively stable with depth-to-water levels in the alluvial aquifer measuring from between approximately 13 feet to 37 feet in the western portion of the sub-basin, 10 feet to 50 feet in the central portion, and 15 feet to 100 feet in the eastern portions of the sub-basin. In the Saugus Formation, depth-to-water levels have also remained stable. In the vicinity of the study corridors adjacent to the Santa Clara River Valley East Sub-basin, recent depth-to-water measurements in USGS wells ranged between 9.60 feet and 10.20 feet (DWR 2003) (Table 5-1).

5.8.5. San Fernando Valley Groundwater Basin (Groundwater Basin Number 4-12)

The San Fernando Valley Groundwater Basin drains a surface area of approximately 145,000 acres (226 square miles). The basin is bounded on the north and northwest by the Santa Susana Mountains, on the north and northeast by the San Gabriel Mountains, on the east by the San Rafael Hills, on the south by the Santa Monica Mountains and Chalk Hills, and on the west by the Simi Hills. This groundwater basin includes the water-bearing formations beneath the San Fernando Valley, Tujunga Valley, Browns Canyon, and the alluvial areas surrounding the Verdugo Hills near La Crescenta and Eagle Rock.

Groundwater in the basin is found in the lower Pleistocene Saugus Formation and the Pleistocene and Holocene alluvium. Groundwater is unconfined with the exception of the western part of the basin and the Sylmar and Eagle Rock areas. The Holocene alluvium reaches thicknesses of approximately 100 feet in the northern part of the basin, 400 feet in the eastern part, 800 feet in the western part, and 900 feet near Burbank. The Saugus Formation is approximately 2,000 to 3,000 feet thick in the eastern and western parts of the basin, and up to approximately 6,400 feet thick in the center of the basin.

Displacement by the Verdugo Fault and/or the Eagle Rock Fault causes groundwater to flow to the south near the mouth of Verdugo Canyon. The Verdugo Fault also acts as a partial barrier that causes a fluctuation in groundwater levels near the Hanson Spreading Grounds. Groundwater levels are also affected by unnamed faults in the Sunland, Chatsworth, and San Fernando areas, and at the mouths of the Little Tujunga and Big Tujunga Canyons. In the northern part of the basin, groundwater movement is affected by the Little Tujunga syncline and folds associated with the Northridge Hills, Mission Hills, and Lopez faults. Other barriers to groundwater movement in the basin are subsurface dams in the Pacoima Wash and in Verdugo Canyon.

Total storage capacity of the San Fernando Valley Groundwater Basin is calculated to be approximately 3,670,000 af. This includes the storage capacity values for the San Fernando, Sylmar, Verdugo, and Eagle Rock Basins. Between approximately 1983 and 2003, water levels have remained relatively stable.

Hydrographs show 1998 groundwater levels roughly equal to 1980 groundwater levels, with the exception of groundwater levels near La Crescenta, which were approximately 60 feet lower than 1980 levels (DWR 2003) (Table 5-1).

TABLE 5-1. WELLS AND GROUNDWATER LEVELS IN THE PROJECT AREA.

Well Number	Groundwater Basin	Depth-to-water Measurements (feet) (date)		
		Low	High	Recent
345701118103601 – 010N012W20C006S*	Fremont	117.85 (03/26/2007)	101.60 (03/27/1978)	117.37 (03/25/2008)

5.9 WATER QUALITY

Water quality is the physical, chemical, and biological characteristics of water, when assessed according to standards related to ecosystem health, the safety of drinking water, and the safety of human contact. The State of California Water Resources Control Board and the nine Regional Boards are responsible for setting policies and developing regulations for the implementation of water quality control programs mandated by federal and state water quality statutes and regulations. Water Quality Control Plans (Basin Plans), developed and implemented by the RWQCBs, consider regional beneficial uses, water quality characteristics, and water quality problems (RWQCB 1994, RWQCB 1995).

Surface and groundwater quality objectives in the study area are described in the Los Angeles Region Water Quality Control Plan and the Water Quality Control Plan for the Lahontan Region. Additional groundwater quality objectives are described in California's Groundwater Bulletin 118. Water quality objectives were established to protect the existing and potential beneficial uses of surface and groundwater.

Beneficial uses are goals or desired uses of a water body as specified in the Basin Plans, and may include existing, proposed or, in some cases, historic uses. In the BRRTP study area, water bodies with designated beneficial uses are listed in Table 5-2.

Beneficial uses for surface waters in the BRRTP area include Municipal and Domestic Supply (MUN), Industrial Service Supply (IND), Industrial Process Supply (PROC), Agricultural Supply (AGR), Ground Water Recharge (GWR), Freshwater Replenishment (FRSH), Hydropower Generation (POW), Water Contact Recreation (REC-1), Non-contact Water Recreation (REC-2), Commercial and Sport Fishing (COMM), Warm Freshwater Habitat (WARM), Cold Freshwater Habitat (COLD), Wildlife Habitat (WILD), Rare, Threatened, or Endangered Species (RARE), Spawning, Reproduction, and/or Early Development (SPWN), and Wetland Habitat (WET).

It may be noted that some designated beneficial uses are obviated by more recent laws and regulations such as those protecting drinking water quality in open reservoirs. In response to increasingly stricter drinking water regulations, many reservoirs that store treated potable water are proposed for covering, which potentially would eliminate some beneficial uses. For example, the proposed covering of the Los Angeles Reservoir to achieve more stringent drinking water quality standards would no longer provide potential for groundwater recharge, neither contact nor non-contact recreation, and/or wildlife habitat, as stated in the Basin Plan.

THIS PAGE INTENTIONALLY LEFT BLANK

TABLE 5-2. BENEFICIAL USES AND SECTION 303(D) LISTING OF SURFACE WATER IN THE BRRTP STUDY CORRIDORS.

E – Existing beneficial use
P – Potential beneficial use
I – Intermittent beneficial use

j – Out of service
k – Public access to reservoir and its surrounding watershed prohibited by LADWP
m – Access prohibited by Los Angeles County DPW in concrete-channelized areas

* State Board Resolution No. 88-63 (Sources of Drinking Water) followed by Regional Board Resolution No. 89-03 (Incorporations of Sources of Drinking Water into the Water Quality Control Plans) states that "All surface and ground waters of the State are considered to be suitable, or potentially suitable, for municipal or domestic waters supply and should therefore be designated by the Regional Boards."

THIS PAGE INTENTIONALLY LEFT BLANK

5.9.1. Surface Water Quality

Each Regional Board has developed narrative or numerical water quality objectives for various parameters. These objectives apply to all inland surface waters, enclosed bays, wetlands and estuaries.

TABLE 5-3. SUMMARY OF WATER QUALITY OBJECTIVES FOR SURFACE WATERS IN THE PROJECT AREA[1]

Water Quality Objective	Lahontan RWQCB	Los Angeles RWQCB
Ammonia (Total)	23 mg/L (1-hour average, at pH 7.0 and 20°C)	23 mg/L (1-hour average, at pH 7.0 and 20°C)
Bacteria (Fecal Coliform)	Not to exceed a log mean of 20/100 ml during 30-day period	Not to exceed a log mean of 200/100 ml (REC-1), 2000/100 ml (REC-2) during 30-day period.
Bioaccumulation	--	Toxic pollutants shall not be present at levels that will bioaccumulate in aquatic life to levels which are harmful to aquatic life or human health.
Biochemical Oxygen Demand	--	Waters shall be free of substances that result in increases in the BOD which adversely affect beneficial uses.
Biostimulatory Substances	Shall not occur in concentrations that promote aquatic growths that adversely affect beneficial uses.	Shall not occur in concentrations that promote aquatic growth to the extent that such growth causes nuisance or adversely affects beneficial uses.
Chemical Constituents	Shall not occur in concentrations that adversely affect beneficial uses.	Shall not contain concentrations in amounts that adversely affect beneficial uses.
Chlorine, Total Residual	Shall not exceed a median value of 0.002 mg/L or a maximum value of 0.003 mg/L (based on daily measurements over 6-month period).	Shall not be present in concentrations that exceed 0.1 mg/L and shall not persist in receiving waters at any concentration that causes impairment of beneficial uses.
Color	Shall not contain coloration that causes nuisance or adversely affects beneficial uses.	Shall not contain coloration that causes nuisance or adversely affects beneficial uses.
Exotic Vegetation	--	Shall not be introduced around stream courses to the extent that such growth causes nuisance or adversely affects beneficial uses.
Floating Material	Waters shall not contain floating material, including solids, liquids, foams, and scum, in concentrations that cause nuisance or adversely affect beneficial uses.	Waters shall not contain floating material, including solids, liquids, foams, and scum, in concentrations that cause nuisance or adversely affect beneficial uses.
Methylene Blue Activated Substances (MBAS)	--	MBAS concentrations shall not be higher than 0.5 mg/L in waters designated MUN.
Mineral Quality[2]	--	TDS: 800 mg/L Sulfate: 150 mg/L Chloride: 100 mg/L Boron: 1.0 mg/L Nitrogen: 5 mg/L SAR[3]: 5 mg/L

Water Quality Objective	Lahontan RWQCB	Los Angeles RWQCB
Nondegradation of Aquatic Communities and Populations	Wetlands shall be free from substances attributable to wastewater & other undesirable discharges; all wetlands shall be free from activities that would substantially impair naturally occurring biological communities.	--
Nitrogen (Total), Nitrate, Nitrite[4]	--	Shall not exceed: Total Nitrogen: 10 mg/L Nitrate: 45 mg/L Nitrite: 1 mg/L
Oil and Grease	Shall not contain oils, greases, waxes, or other materials in concentrations that result in visible film or coating on water surface of objects, that cause nuisance or adversely affect beneficial uses.	Shall not contain oils, greases, waxes, or other materials in concentrations that result in visible film or coating on water surface of objects, that cause nuisance or adversely affect beneficial uses.
Oxygen, Dissolved	One day minimum not to be less than: WARM: 3.0 mg/L WARM & SPWN: 5.0 mg/L COLD: 4.0 mg/L COLD & SPWN: 8.0 mg/L	Not to be less than 5.0 mg/L, or: WARM: 5 mg/L COLD: 6 mg/L COLD & SPWN: 7 mg/L
Pesticides	Waters designated MUN shall not contain concentrations in excess of those specified in Table 64444-A of Section 64444 of Title 22 of the California Code of Regulations.	Waters designated MUN shall not contain concentrations in excess of those specified in Table 64444-A of Section 64444 of Title 22 of the California Code of Regulations.
pH	Determined on a case-by-case basis; in general, pH must range from 6.5 – 8.5.	Ambient pH levels shall not be changed more than 0.2 units from natural conditions as a result of waste discharge.
Polychlorinated Biphenyls (PCBs)	--	The purposeful discharge of PCBs is prohibited. Uncontrollable discharges are limited to 70 pg/L (for protection of human health) and 14 ng/L (for protection of aquatic life).
Radioactive Substances	Shall not occur in concentrations in excess of those specified in Table 4 of Section 64443 of Title 22 of the California Code of Regulations.	Shall not occur in concentrations in excess of those specified in Table 4 of Section 64443 of Title 22 of the California Code of Regulations.
Sediment	Suspended sediment load and suspended sediment discharge rate shall not be altered in such a manner as to cause nuisance or adversely affect beneficial uses.	--
Solid, Suspended, or Settleable Materials	Waters shall not contain substances or settleable materials in concentrations that cause nuisance or adversely affect beneficial uses.	Waters shall not contain substances or settleable materials in concentrations that cause nuisance or adversely affect beneficial uses.
Taste and Odor	Waters shall not contain taste or odor-producing substances in concentrations that cause nuisance or adversely affect beneficial uses.	Waters shall not contain taste or odor-producing substances in concentrations that cause nuisance or adversely affect beneficial uses.

Water Quality Objective	Lahontan RWQCB	Los Angeles RWQCB
Temperature	Temperature of WARM waters shall not be altered by more than 5° F above of below the natural temperature; temperature of COLD waters shall not be altered.	Temperature of WARM waters shall not be altered by more than 5° above natural temperature, and shall not be raised above 80° as result of waste discharges. Temperature of COLD waters shall not be altered by more than 5° above the natural temperature.
Toxicity	Waters shall not contain toxic substances in concentrations that are toxic to, or produce detrimental physiological responses in human, plant, animal, or aquatic life.	Waters shall not contain toxic substances in concentrations that are toxic to, or produce detrimental physiological responses in human, plant, animal, or aquatic life.
Turbidity	Waters shall be free of changes in turbidity that cause nuisance or adversely affect beneficial uses; increases in turbidity shall not exceed natural levels by more than 10 percent.	Waters shall be free of changes in turbidity that cause nuisance or adversely affect beneficial uses. Controllable increases in turbidity shall not exceed 20% where natural turbidity is between 0 and 50 NTU, and 10% where natural turbidity is greater than 50 NTU.

1. For details, see Chapter 3 of the Basin Plans for the Lahontan RWQCB and the Los Angeles RWQCB.
2. Applies to the Santa Clara River between Lang Gauging Station and Bouquet Canyon Road bridge.
3. SAR – Sodium Adsorption Ratio.
4. For surface waters within the Project Area except Santa Clara River.

Under Section 303(d) of the CWA, states, territories, and authorized tribes are required to develop a list of water quality limited segments. These waters on the list do not meet water quality standards, even after point sources of pollution have installed the minimum required levels of pollution control technology. The law requires that these jurisdictions establish priority rankings for water on the lists and develop action plans, called Total Maximum Daily Loads (TMDL), to improve water quality.

On July 25, 2003, the EPA gave final approval to California's 2002 Section 303(d) List of Water Quality Limited Segments. Section 303(d)-listed or impaired streams and completed TMDL requirements are identified as part of the resource inventory of the Project area. Impaired streams are considered sensitive resources in the routing of transmission lines and are protected from water quality impacts.

Table 5-4 presents a list of impaired water bodies in the Project area. All impaired waters in the Project area are within the jurisdiction of the Los Angeles RWQCB; no Section 303(d)-listed impaired water bodies within jurisdiction of the Lahontan RWQCB occur in the Project area.

TABLE 5-4. SECTION 303(D) LIST WATER QUALITY IMPAIRED WATERS REQUIRING TMDLS* IN THE PROJECT AREA

Name	Pollutants/Stressor	Potential Sources	Estimated Area Affected
Dry Canyon Creek	Fecal Coliform	Urban Runoff/Storm Sewers Natural Sources	3.9 miles
Elizabeth Lake	Eutrophic Organic Enrichment/Low Dissolved Oxygen pH Trash	Nonpoint Source	123 acres
Lake Hughes	Algae Eutrophic Fish Kills Odor Trash	Nonpoint Source	21 acres

Name	Pollutants/Stressor	Potential Sources	Estimated Area Affected
Munz Lake	Eutrophic Trash	Nonpoint Source	6.6 acres
Santa Clara River Reach 7 (Bouquet Canyon Road to above Lang Gauging Station)	Coliform Bacteria	Nonpoint/Point Source	21 miles

*2006 CWA Section 303(d) List of Water Quality Limited Segments Requiring TMDLs.

5.9.2. Groundwater Quality

Fremont Valley Groundwater Basin.

In the southwest part of the basin, groundwater is typically sodium bicarbonate or calcium-sodium sulfate in character, with total dissolved solids (TDS) ranging between 800 milligrams per liter (mg/L) to 1,000 mg/L. Portions of the basin are impaired by fluoride, sodium, and chloride (DWR 2003).

Antelope Valley Groundwater Basin.

Groundwater in the northern, southern, and central portions of the basin is typically calcium bicarbonate in nature, and is sodium bicarbonate or sodium sulfate in nature in the central portion. The eastern part of the basin is typically sodium-calcium bicarbonate in nature in the upper aquifer and sodium bicarbonate in nature in the lower aquifer. Throughout the basin, TDS range from 200 mg/L to 800 mg/L. Groundwater throughout the basin is impaired by high levels of boron and nitrate (DWR 2003).

Acton Valley Groundwater Basin.

Groundwater is generally calcium bicarbonate in nature, with TDS ranging from 424 mg/L to 712 mg/L. The northern portion or the basin is impaired by high concentrations of TDS, sulfate, and chloride. Some of these concentrations exceed drinking water standards (DWR 2003).

Santa Clara River Valley East Sub-basin.

Groundwater varies from calcium bicarbonate in the eastern part of the sub-basin to calcium sulfate in the west, and nitrate content decreases from east to west. In the East Sub-basin, TDS range from 550 mg/L to approximately 1,000 mg/L. Some parts of the sub-basin are impaired by nitrate, TDS, trichloroethylene, and ammonium perchlorate (DWR 2003).

San Fernando Valley Groundwater Basin.

Groundwater character varies from calcium sulfate-bicarbonate in the western portion of the basin to calcium bicarbonate in the eastern portion, with TDS ranging from 326 mg/L to 615 mg/L throughout. Groundwater in this basin is impaired by volatile organic compounds (VOCs) such as trichloroethylene, perchloroethylene, petroleum compounds, chloroform, nitrate, sulfate, and heavy metals (DWR 2003).

6.0 IMPACT ASSESSMENT

Initial impact levels of each segment were evaluated by combining resource sensitivity and access level category (i.e., level of impact expected from ground disturbance). All known water resources within the study corridors of each segment were inventoried and evaluated to determine potential impacts resulting from the Project.

Impacts to inventoried water resources were evaluated considering the following factors:

1. Construction, operation, and maintenance related impacts
2. Occurrence of affected water resource areas
3. Water resource sensitivity levels
4. Access level category (level of impact expected from ground disturbance)
5. Mitigation measures to reduce initial impact levels

6.1 IMPACT MODEL

To determine the intensity of Project-related impacts, an impact model was developed for water resources. The impact assessment model combines resource sensitivity and access levels The combination of these assessment variables determined the level of impact (high, moderate, low). The results of the impact assessment are presented in detail in Section 7.0 of this report.

Once initial impacts levels were established for each segment, specific measures for mitigating or reducing predicted high- or moderate-level impacts were applied, as required by CEQA §15126.4 Residual impacts are the impacts remaining after applying mitigation measures.

6.2 RESOURCE SENSITIVITY

Resource sensitivity is the measure of the probable adverse effect that a resource would experience through direct or indirect impacts associated with construction, operation, and maintenance of the Project. Adverse effects to water resources were assessed using three major criteria: the susceptibility of the resource to the potential changes resulting from construction, operation, and maintenance activities; significance of the potential change on the resource; and occurrence or abundance of affected water resources within the study area. Also considered were hydrological capacity, accessory benefits (e.g., plant and wildlife habitat), and potential to affect engineering and design.

Determination of Potential Change
Changes are brought about by construction of the Project, the physical presence and operation of the Project facilities, and management and maintenance of the Project facilities. This potential for change is predicted by evaluating environmental conditions, the Project description, and implementation specifications.

Significance of Changes
The effect of potential changes on resources is described in levels of significance. The significance of any change relates to the immediate- and long-term effects that the change may have, either directly or indirectly, on the resource. Accordingly, a sensitivity value of maximum, moderate, or minimal was assigned to each resource to represent the potential level of significance.

6.2.1. Sensitivity Values

Sensitivity values are based on the function and value of the resource, and the level of impacts to that resource. For example, Palustrine Forested (PFO) wetlands are designated at a maximum sensitivity level because they provide high functional values and would be permanently impacted by clearing, ROW maintenance, and filling for access road construction.

A **maximum** sensitivity value was assigned to:

- areas with occurrences of perennial rivers or streams, including Lower Perennial Riverine (R2) wetlands
- Palustrine Emergent (PEM) or PFO wetlands
- Riparian Conservation Areas (RCAs)

A **moderate** sensitivity value was assigned to:

- 100-year floodplains
- intermittent rivers and streams, including Intermittent Riverine (R4) wetlands
- partially hydric soils
- Significant Ecological Areas (SEAs)

A **minimal** sensitivity was assigned to:

- Palustrine Unconsolidated Bottom (PUB) wetlands
- Aqueducts
- Wells and groundwater

Lands not associated with a water resource feature or indicator were not considered sensitive.

Access Levels and Ground Disturbance

The criteria for assessing the initial ground disturbance impacts to water resources are summarized in Table 6-1. Access level categories and resource sensitivity levels were the main factors used in estimating potential impact levels. Classifications for access level categories (e.g., ground disturbance), along with other Project ground disturbance estimates, are located in Appendix C.

TABLE 6-1. WATER RESOURCES IMPACTS BY ACCESS LEVEL CATEGORY

Resource		Access Level Categories						
		1	2	3	4	5	6	H
Perennial river or stream		Low	Low	Moderate	High	High	High	High
Intermittent river or stream		Low	Low	Moderate	Moderate	High	High	High
Aqueduct		Low	Low	Moderate	High	High	High	High
Wells		Low	Low	Low	Low	Low	Low	Low
Riparian habitat and RCAs		Low	Moderate	High	High	High	High	High
SEAs		Low	Low	Moderate	Moderate	High	High	High
NWI wetland	PEM	Low	Moderate	High	High	High	High	High
	PFO	Low	Moderate	High	High	High	High	High
	PUB	Low	Low	Moderate	Moderate	High	High	High
	R2	Low	Low	Moderate	High	High	High	High
	R4	Low	Low	Moderate	Moderate	High	High	High
Partially hydric soils		Low	Low	Moderate	Moderate	High	High	Moderate
100-year floodplain		Low	Low	Moderate	Moderate	High	High	Moderate

6.3 IMPACT LEVELS

Water resources impact determinations are based on significance criteria derived from CEQA Guidelines (Appendix G, Environmental Checklist Form, Section IX). Impacts are considered significant if the Project:

- Violates any water quality standards or waste discharge requirements, creates new sources of polluted runoff, or otherwise substantially degrades water quality.
- Substantially depletes groundwater supplies or interferes substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted).
- Substantially alters the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site.
- Substantially alters the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increases the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.
- Creates or contributes runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provides substantial additional sources of polluted runoff.
- Has a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means.
- Places housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map.
- Places within a 100-year flood hazard area structures which would impede or redirect flood flows.
- Exposes people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam.
- Results in or is subject to damage from inundation by seiche, tsunami, or mudflow.

6.4 IMPACT ASSESSMENT METHODOLOGY

6.4.1. 230 kV Transmission Line

To assess impacts to water resources associated with the new 230 kV transmission line, each water resource within 0.5 mile of the proposed centerline was mapped at a scale of 1:24,000 using GIS. Based on this map, location-specific analyses of temporary and permanent impacts could be made, and after considering the inherent sensitivity of perennial streams, intermittent streams, NWI wetlands, and other water resources that could be affected, a determination was made of whether high, moderate, or low impacts would result. This analysis was conducted throughout all Project segments.

For each of the initially proposed segments, the presence of streams, wetlands, aqueducts, wells, riparian habitat, RCAs and SEAs, hydric soils, and 100-year floodplains within one-half mile of the centerline was determined to the nearest tenth of a mile, and mile marker begin/end points were recorded. Permanent and temporary impacts to each resource (in acres) were determined based on the ground disturbance level applicable to the location evaluated. Permanent disturbance within the ground disturbance areas would be limited to the tower foundations and the footprint of new access roads. All other ground disturbance would be temporary.

All initial probable 230 kV component impacts were re-assessed in light of the effectiveness of General Practices (GPs) and Mitigation Measures (MMs) to reduce potential impacts. As summarized in Table 6-1, the initial 230 kV Project impacts were assessed with consideration to the sensitivity of each water resource type. After assigning initial ground disturbance impact levels for all water resources traversed by the 0.5-mile corridor for the centerline, GPs and MMs were considered and the degree to which they would reduce the initial impact was evaluated. GPs and MMs were then applied, as appropriate, to reduce the level of residual impacts to each water resource.

6.4.2. New 230 kV Circuit

In the Castaic Transmission Corridor, LADWP has two existing parallel double-circuit 230 kV towers. The northern towers hold the Castaic-Olive 230 kV Transmission Line and the second position is vacant. LADWP proposes the addition of approximately 12 miles of a new 230 kV transmission circuit onto existing Castaic – Olive 230 kV Transmission Line structures (towers 1-1 through 12-1).

Water resources within one half mile of towers 1-1 through 12-1 of the existing Castaic-Olive 230 kV transmission line were inventoried to the nearest tenth of a mile and mile marker begin/end points were recorded. This information was used to determine permanent impacts that would result from upgrading the existing access and spur roads and clearing of the right-of-way. Temporary impacts would occur where equipment staging, line work, or construction traffic access would be needed.

6.4.3. Reconductoring

As part of the BRRTP, LADWP is proposing to upgrade the existing BR-RIN line from the Barren Ridge Switching Station to the Rinaldi Substation with larger-capacity conductors. Permanent impacts would occur from rehabilitation of the existing access and spur roads, and clearing of the right-of-way. By utilizing the existing structures and ROW, the Project would minimize permanent impacts while allowing additional transmission capacity along the corridor. Temporary impacts would occur where equipment staging, line work, or construction traffic access would be needed. Upgrading the existing BR-RIN would involve approximately 13 miles of USFS lands and four miles of BLM lands.

6.4.4. New Haskell Canyon Switching Station

Ground disturbance at the Haskell Canyon Switching Station site would lead to permanent impacts within the proposed switching site fence line and associated new access roads. The station would require an area of approximately 400 feet by 600 feet to accommodate the necessary equipment such as steel support structures, circuit breakers, disconnect switches, and associated equipment, and a relay house and control house containing control and protective relaying equipment. Temporary impacts within the area would occur where equipment staging, line work, or construction traffic access would be needed.

6.4.5. Expansion of Barren Ridge Switching Station

Expansion of the Barren Ridge Switching Station site would lead to permanent impacts within the proposed site fence line. LADWP proposes expansion of the existing Barren Ridge Switching Station to the east side by 235 feet by 500 feet for a total station size of 485 feet by 500 feet (approximately 5.6 acres). Existing access roads will be used and permanent impacts will be restricted to the site expansion. Temporary impacts within the area would occur where equipment staging, line work, or construction access would be needed.

6.5 IMPACTS AND MITIGATION PLANNING

Potential impacts to water resources include temporary (construction-related) impacts and long-term (permanent) impacts. When evaluating potential impacts to water resources, it was assumed that the Project would comply with all applicable federal, state, and local regulatory requirements that protect surface water and groundwater.

The GPs described in Table 6-2 below are measures that would be included in the Project description and implemented as part of the proposed Project. Impact analysis assumed that all GPs will be implemented as defined.

The USFS, Pacific Southwest Region has established water quality protection BMPs and BMP evaluation protocols for use on Forest lands. The GPs and Mitigation Measures described in this section have been developed with Forest Service BMPs in mind, where applicable. For example, GP-5 and GP-9 are comparable to Forest Service BMPs Practice 2-12, Servicing and Refueling of Equipment, and Practice 7-4, Forest and Hazardous Spill Prevention Control and Countermeasure (SPCC) Plan (USFS 2000).

The specifically recommended Mitigation Measures described in Table 6-3 below would be used on a site-specific basis to minimize Project-related impacts if it is determined that GPs would not fully mitigate the impacts for which they are presented.

TABLE 6-2. GENERAL PRACTICES

Plans	
GP-1	**Plan of Development & Construction, Operation and Maintenance Plans.** In consultation with the Forest Service and BLM Authorizing Officers prior to construction, LADWP shall develop a Construction, Operation and Maintenance Plan (COM Plan) with the Forest Service and Plan of Development (POD) with BLM. These plans shall be attached to and become a part of the Special Use and Right-of-Way Authorizations. The COM Plan and POD shall include, at a minimum, road maintenance specifications, vegetation treatment and rehabilitation specifications, and conditions on maintenance and replacement of improvements. The agencies may combine the POD and COM plans into a single document for the project.
GP-3	**Hazardous Materials/Waste Management Plan.** A project-specific hazardous materials management and hazardous waste management program will be developed prior to initiation of the project. The program will outline proper hazardous materials use, storage and disposal requirements as well as hazardous waste management procedures. The program will identify types of hazardous materials to be used during the project and the types of wastes that will be generated. All project personnel will be provided with project-specific training. This program will be developed to ensure that all hazardous materials and wastes were handled in a safe and environmentally sound manner. Hazardous wastes will be handled and disposed of according to applicable rules and regulations. Employees handling wastes will receive hazardous materials training and shall be trained in hazardous waste procedures, spill contingencies, waste minimization procedures and Treatment, Storage and Disposal Facility (TSDF) training in accordance with OSHA Hazard Communication Standard and 22 CCR. If degraded soil or groundwater is encountered during excavation (e.g., there is an obvious sheen, odor, or unnatural color to the soil or groundwater), it shall be excavated, tested, and disposed of in accordance with state hazardous waste disposal requirements. The Plan shall also include procedures detailing emergency responses to releases of hazardous materials. It will prescribe hazardous materials handling procedures for reducing the potential for a spill during construction, and will include an emergency response program to ensure quick and safe cleanup of accidental spills. All hazardous materials spills or threatened release, including petroleum products such as gasoline, diesel, and hydraulic fluid, regardless of the quantity spilled, will be immediately reported to the appropriate agency as outlined in the Plan if the spill has entered a navigable water, stream, lake, wetland, or storm drain, if the spill impacted any sensitive area including conservation areas and wildlife preserves, or if the spill caused injury to a person or threatens injury to public health. All construction personnel, including environmental monitors, will be aware of state and federal emergency response reporting guidelines.
GP-5	**Stormwater Pollution Prevention Plan.** A project-specific Construction Stormwater Pollution Prevention Plan (SWPPP) will be prepared and implemented prior to the start of construction. The SWPPP will utilize Best Management Practices (BMPs) to address the storage and handling of hazardous materials and sediment runoff during construction activities.

GP-6	**Spill Prevention, Countermeasure, and Control Plan.** LADWP will prepare or update existing Spill Prevention, Countermeasure, and Control Plan (SPCC Plan) for proposed and/or expanded switching stations if necessary or required by EPA guidelines. The plans will include engineered and operational methods for preventing, containing, and controlling potential fluid releases, and provisions for quick and safe cleanup.
GP-7	**Soil Management Plan.** A Soil Management Plan will be developed and implemented for construction of the proposed Project. The objective of the Soil Management Plan is to provide guidance for the proper handling, onsite management, and disposal of impacted soil that might be encountered during construction activities. The plan will include practices that are consistent with California Title 8, Occupational Safety and Health Administration (Cal-OSHA) regulations, as well as appropriate remediation standards that are protective of the planned use. The Plan will provide guidelines for identification of impacted soil, assessing impacted soil, soil excavation, impacted soil storage, verification sampling, and impacted soil characterization and disposal. In the event that potentially contaminated soils are encountered within the footprint of construction, soils will be tested and stockpiled. The appropriate Certified Unified Program Agency (CUPA) will determine whether further assessment is warranted.
Design	
GP-11	Project features will be placed so as to avoid sensitive features including, but not limited to, riparian areas, water courses, and cultural sites, and/or to allow conductors to clearly span the features, within limits of standard tower design. This will minimize the amount of sensitive features disturbed and/or reduce visual contrast.
GP-12	Drainage control features will be installed, as appropriate, to minimize the amount of stormwater flow from areas of active construction. Details would be described in the SWPPP.
Construction Vehicles/Equipment	
GP-15	All trucks hauling soils or other loose materials shall be covered, or maintain at least two feet of freeboard (distance between the material and the top of the truck).
GP-16	Where visible soil material is carried onto adjacent public streets, the affected streets shall be cleaned daily with water sweepers.
GP-17	All vehicles and equipment operating within 100 feet of an active stream will be inspected daily to ensure they are free of any leaks of fuel, cooling, or lubricating fluids.
GP-18	All construction vehicles shall maintain a hazardous materials spill kit, which shall include absorbent materials, tarps, small storage containers or waterproof bags, and latex gloves. Field personnel shall be made aware of these kits and instructed on how to use them.
GP-19	Refueling, or addition or changing of oil and other fluids for equipment and heavy machinery shall be performed only at approved staging and construction yards. Staging and construction yards will be located on upland sites and spill containment measures will be used to minimize risk of spill or drainage into waterways. Oil and other fluids will be disposed of as required by California law. Emergency refueling, or emergency addition or changing of oil or other fluids shall not be performed within 500 feet of natural stream channels or wetlands.
GP-20	Helicopters utilized for construction will be refueled at helicopter staging areas or local airports. Procedures will include the use of drop cloths made of plastic and drip pans and trays to be placed under refilling areas to ensure that chemicals do not come into contact with the ground. Refueling areas will be located in designated areas where absorbent pads and trays are available.
Access Roads	
GP-23	The alignment of any new access roads or overland routes shall follow the designated area's landform contours where possible, providing that such alignment does not additionally impact resource values.
GP-24	To the extent practical, any re-grading of access roads shall be the minimum necessary to provide safe access of construction equipment, and erosion control measures.
GP-25	Construction vehicles shall use paved roads to access the construction site when available.
GP-33	In areas where soils and vegetation are particularly sensitive to disturbance, existing access roads would be repaired only in areas where they are otherwise impassable or unsafe.

Construction Areas	
GP-34	Construction activities shall be limited to the designated right-of-way and approved access and work areas as identified in the ROD and POD. Any deviations from the approved areas must be cleared with the jurisdictional agency and/or landowner.
GP-35	Grading areas shall be clearly marked and no equipment or vehicles shall disturb slopes or drainages outside of the grading area.
GP-36	No paint or permanent discoloring agents will be applied to rocks or vegetation to indicate survey or construction activity limits.
GP-37	In construction areas (e.g., marshalling yards, tower sites, spur roads from existing access roads) where ground disturbance is significant or where recontouring is required, surface restoration shall occur as required by the landowner or land management agency. The method of restoration will normally consist of returning disturbed areas back to their natural contour, reseeding, installing cross drains for erosion control as necessary, placing water bars in the road as necessary, and filling ditches.
GP-38	Soil excavated from construction activities shall not be left at work areas where the slopes exceed 10 percent or where the work area is within 100 feet of a natural stream or waterbody (receiving water). In these situations, loose soil shall be used elsewhere within the immediate area or stockpiled at the staging area. Stockpiled soil shall be managed as required by the SWPPP. No stockpiling or spreading of soil or other materials shall occur within stream channels.
GP-39	During grading or excavation work for the Project, the contractor shall observe the exposed soil for visual evidence of contamination. If visual contamination indicators are observed during construction, the contractor shall stop work until the material is properly characterized and appropriate measures are taken to protect human health and the environment. The contractor shall document the exact location of the contamination and shall immediately notify a designated Environmental Monitor and propose actions for addressing the contamination in accordance with the Soil Management Plan.
GP-40	Existing watering facilities (e.g., tanks, developed springs, water lines, wells, etc.) will be repaired or replaced, if they are damaged or destroyed by construction activities, to their pre-disturbed condition as required by the landowner or land management agency.
GP-41	Allow natural vegetation to reoccur on temporarily disturbed areas following the completion of construction.
GP-43	Every effort will be made to minimize vegetation removal and permanent loss at construction sites. Native vegetation will be flagged for protection or stockpiled for recontouring use at the discretion of the Biological Monitor and the Construction Supervisor.
GP-44	In construction areas where recontouring is not required, vegetation will be left in place wherever possible and the original contour will be maintained to avoid excessive root damage and allow for resprouting. Disturbance will be limited to overland driving where feasible to minimize changes in the original contours.
GP-45	Use of heavy equipment within a flowing channel will be avoided if possible; however, should it be necessary, the Environmental Monitor will be notified prior to initiation of construction activities to allow adequate time for site visits and surveys, if necessary.
GP-46	Asphalt or cement equipment will not be rinsed in, nor excess products deposited into any stream or other waterway. Asphalt or concrete effluent will not be allowed to enter into stream or RCA. Effluent will be removed from standing water and prevented from entering a waterway.
GP-47	Fill material, including brush, loose soils, and other similar debris will not be deposited within a stream channel or on a stream bank.

Surveys/Monitoring	
GP-48	**Biological Monitor.** For areas identified as environmentally sensitive, such as streams, wetlands, riparian areas, and other environmentally sensitive areas, a biological monitor shall be present during ground disturbing construction activities. The qualified biologist shall conduct monitoring for any area subject to disturbance from construction activities that may impact biological resources. The biological monitor's duties include minimizing impacts to special-status species, native vegetation, wildlife habitat, and unique resources, as well as to identify potential issues or impacts to biological resources and report those to the authorized biologist. Where appropriate, the monitor will flag the boundaries of biologically sensitive areas and monitor any construction activities in these areas to ensure that ground disturbance activities and impacts occur within designated limits.
GP-49	**Worker Environmental Awareness Program.** A Worker Environmental Awareness Program (WEAP) will be implemented to educate all construction personnel of the area's environmental conditions and the environmental protection measures that must be adhered to. An environmental training program will be established to communicate environmental concerns and appropriate work practices, including spill prevention, emergency response measures, protection of biological and cultural resources, and proper Best Management Practice (BMP) implementation, to all construction and maintenance personnel.
Coordination/Permits	
GP-50	Prior to construction, LADWP shall consult with all federal, state, and local agencies, including local agency consortiums, having jurisdiction over lands affected by the proposed Project's ROW and ancillary facilities to ensure that no permanent restrictions or preclusions of their land management practices occur.
GP-53	Incorporate riparian area avoidance and permit measures. The following actions and all permit conditions detailed within the Nationwide 12 permit and RWQCB 401 water quality certification (subject to separate approval) would be implemented by the construction manager and environmental compliance monitor(s). Before construction, qualified resource specialists would stake and flag or fence exclusion zones around all identified riparian woodlands. Such exclusion zones would include a 10-foot buffer to preclude sediment intrusion into the riparian areas. Earth-moving activities would be restricted from these zones, although essential vehicle operation and foot travel would be permitted on existing roads, bridges, and crossings. All other construction activities, vehicle operation, material and equipment storage, and other surface-disturbing activities would be prohibited within the exclusion zone. In areas where riparian habitats are unavoidable, the construction manager in consultation with the lead environmental compliance inspector would narrow the width of the centerline to the maximum extent allowable. New spur roads and existing access road improvements would be constructed and implemented using methodology that preserves existing hydrology. Tower pad clearance would be minimized to the maximum extent allowable. All temporarily disturbed riparian areas that would not be utilized for future routine operation and maintenance activities would be restored to ensure no net loss of habitat functions and values. Following construction activities, the areas would be restored as soon as practicable.
GP-54	Construction crews will avoid impacting the streambeds and banks of any streams along the route to the extent feasible. When construction or maintenance work affects the bed, bank or margins of a stream under CDFG jurisdiction, LADWP will notify CDFG as required under Fish and Game Code Section 1602, which may include securing a Streambed Alteration Agreement.

TABLE 6-3. SPECIFICALLY RECOMMENDED MITIGATION MEASURES.

Measure	Description
HYD – 1	For Project construction and operation, off-road or cross-country access routes shall be preferred, as feasible, over the construction of new access roads. Such access roads would be approved in advance by the Environmental Monitor and the Project Manager and be flagged with easily seen markers. Any new access roads shall be constructed by mowing or crushing, rather than blading, wherever possible. Mowing for temporary or permanent access roads shall be limited to a 12 foot wide area on straight portions of the road (slightly wider on turns), and the mowing height shall be no less than 4 inches from finished grade. Existing crossings shall be utilized at perennial streams, wetlands, and irrigation channels to the extent feasible. New access roads not required for ongoing maintenance shall be permanently closed after construction using the most effective and least environmentally damaging methods appropriate to that specific area, with concurrence of the landowner or land manager (e.g., stockpiling and replacing topsoil, or rock replacement).
HYD – 2	Roads would be built as near as possible to right angles to the streams and washes, if feasible. Culverts would be installed where necessary. All construction and maintenance activities shall be conducted in a manner that would minimize disturbance to vegetation, drainage channels, and intermittent or perennial stream banks. In addition, road construction would include dust-control measures during construction in sensitive areas. All existing roads would be left in a condition equal to or better than their condition prior to the construction of the transmission line.
HYD – 3	New impervious areas associated with temporary construction would be restored to existing conditions, including but not limited to revegetation, to the extent possible after completion of Project construction.
HYD – 4	Stormwater drainage inside switching station walls would be designed to minimize erosion and increase sediment control. Internal runoff would be released from the switching station by means of surface drainage structures designed to filter contaminants from water flow. Drainage from the property would be collected and controlled by surface improvements, as detailed in the SWPPP.
HYD – 5	Structures and new access roads placed within a 100-year floodplain would be engineered so that they do not impede or redirect flood flows or raise the flood elevation.
HYD – 6	Structures located within the 100-year floodplain of rivers and streams would be designed to minimize the capture of flood debris to prevent flow obstructions and scouring during flood flows.
HYD – 7	Structures located adjacent to or downslope of lakes and reservoirs would be designed to minimize damage from inundation of a seismic seiche.
HELICOPTER	Helicopter Mitigation shall be implemented in steep areas of the Angeles National Forest where access is limited. During final design of the Project, areas other than those currently identified on Alternatives 1 and 2a may potentially require helicopter construction of the towers. This determination would generally be made where tower sites have no existing access roads within 300 feet and slopes are greater than 25 percent. Final identification of these tower sites would be determined and agreed upon by USFS, BLM and LADWP.

6.5.1. Types of Impacts

Below are descriptions of the criteria in which an impact would be determined significant.

Construction-related Impacts

Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.

Temporary impacts to water quality could result from stormwater runoff during construction of the Project. Construction of the transmission line and the new Haskell Canyon Switching Station, expansion of the Barren Ridge Switching Station, and reconductoring of the existing BR-RIN line would require ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction. Disturbed soils accelerate erosion and increase sediment in stormwater runoff to receiving waters, causing increased turbidity and sedimentation. Dewatering during construction activities could potentially release contaminated groundwater to surface water channels or drainage features. Additionally, fuel, oil, and other fluids used in construction vehicles, equipment, and heavy machinery could enter streams and contaminate water. Potential impacts to water quality from sedimentation, turbidity, and oil/chemical contamination would be less than significant. Application of GPs such as GP-5, GP-7, GP-12, and GP-19, and implementation of HYD-1 would further reduce these potential impacts.

HYD-1 would minimize the potential for erosion, sedimentation, and increased turbidity by restricting where roads may be sited, minimize the use of blading for new road construction, and requiring the use of existing stream crossings, where feasible.

Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.

Construction of the transmission line and the new Haskell Canyon Switching Station, expansion of the Barren Ridge Switching Station, and reconductoring of the existing BR-RIN line would require ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction. This ground disturbance could potentially alter drainage patterns within the work areas and result in soil erosion leading to increased sedimentation. Potential impacts resulting from substantial drainage pattern alteration would be significant without mitigation. Implementation of mitigation measures HYD-1, HYD-2, and HELICOPTER would reduce potential impacts resulting from substantial drainage pattern alteration to less than significant.

Substantial alteration of existing drainage patterns, including through the alteration of the course of a stream or river, or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.

Construction of the transmission line and the new Haskell Canyon Switching Station, expansion of the Barren Ridge Switching Station, and reconductoring of the existing BR-RIN line would require ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction. The proposed transmission line would cross numerous streams and drainages, including the Santa Clara River. Ground disturbance related to construction of the proposed transmission line could potentially alter drainage patterns within the work areas and result in an increase of the rate or amount of surface water runoff. Potential impacts resulting from flooding through alteration of existing drainage patterns would be significant without mitigation. Implementation of mitigation measures HYD-1, HYD-2, and HELICOPTER would reduce potential impacts resulting from runoff or flooding through alteration of existing drainage patterns to less than significant.

HYD-2 reduces potential impacts to existing drainage patterns of streams and washes by requiring new permanent or temporary roads to be constructed in a manner that would minimize disturbance to vegetation, drainage channels, and intermittent or perennial stream banks.

HELICOPTER mitigation would, where implemented, reduce the need for access roads to be constructed on very steep slopes. This would minimize alteration of drainage patterns, as well as related erosion, siltation, and flooding.

Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems or contribution of substantial additional sources of polluted runoff.

Construction of the transmission line and the new Haskell Canyon Switching Station, expansion of the Barren Ridge Switching Station, and reconductoring of the existing BR-RIN line would require ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction. Creation of new permanent access and spur roads or widening of existing roads would potentially create additional sources of runoff. Likewise, grading activities for construction of the new Haskell Canyon Switching Station and extension of the existing Barren Ridge Switching Station would potentially contribute additional sources of polluted runoff. These potential impacts would be significant without mitigation.

Potential impacts related to contribution of substantial additional sources of polluted runoff would be less than significant. Application of GPs such as GP-5 would further reduce these potential impacts.

Have substantial adverse effect on federal protected wetlands as defined by Section 404 of the Clean Water Act through direct removal, filling, hydrological interruption, or other means.

Construction of the transmission line and the new Haskell Canyon Switching Station, expansion of the Barren Ridge Switching Station, and reconductoring of the existing BR-RIN line would require ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction. Construction of the new Haskell Canyon Switching Station and expansion of the existing Barren Ridge Switching Station may also require importation of soil for filling activities. These activities could impact wetlands by removing wetland vegetation and soils, or by filling wetlands with upland soils and destroying hydrological connectivity.

Potential impacts to federal protected wetlands would be less than significant. Application of GPs such as GP-49 would further reduce these potential impacts.

Operation- and Maintenance-related Impacts

Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial additional sources of polluted runoff.

Construction of the new Haskell Canyon Switching Station and expansion of the existing Barren Ridge Switching Station would create new impermeable surfaces with the potential to increase the rate of stormwater runoff and contribute additional sources of polluted runoff. Maintenance of access roads and structure pads (e.g., gravelling, vegetation clearance) would also contribute additional sources of stormwater runoff. Blading and other methods of vegetation removal for clearance of roads and construction areas would decrease the ability of the soil to absorb water and increase stormwater runoff from disturbed areas. Increased runoff could result in increased erosion, and siltation and flooding downstream of the disturbed areas. Implementation of mitigation measures HYD-3 and HYD-4 would reduce these potential impacts to less than significant.

HYD-3: New impervious areas associated with temporary construction will be restored to existing conditions, including but not limited to revegetation, to the extent possible after completion of Project construction.

HYD-4: Stormwater drainage inside switching station will be designed to minimize erosion and increase sediment control, as detailed in the SWPPP.

Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.

Construction of the new 230 kV transmission line would result in the placement of tower structures within 100-year flood hazard areas. Structures placed in these areas could potentially impede flood flows or redirect flood flows to areas not currently within a flood hazard area by raising the base flood elevation level. Implementation of mitigation measures HYD-5 and HYD-6 would reduce potential impacts resulting from impeding or redirecting flood flows to less than significant.

HYD-5: Structures and new access roads placed within a 100-year floodplain will be engineered so that they do not impede or redirect flood flows or raise the flood elevation.

HYD-6: Structures located within the 100-year floodplain of rivers and streams will be designed to minimize the capture of flood debris to prevent flow obstructions and scouring during flood flows.

Result in or be subject to damage from inundation by seiche, tsunami, or mudflow.

Segments of the new 230 kV transmission line and a portion of the existing BR-RIN line would be located adjacent to bodies of water capable of producing a seiche during or following a seismic event, and would potentially be subject to damage from inundation.

Implementation of mitigation measure HYD-7 would reduce potential impacts resulting from damage or destruction of tubular steel pole (TSP) or lattice structures during a seismic seiche to less than significant.

HYD-7: Structures located adjacent to lakes and reservoirs will be designed to minimize damage resulting from inundation from a seismic seiche.

Other Potential Impacts

Potential Project-related impacts resulting from construction, operation, and maintenance were assessed with regards to the following significance criteria. As discussed below, the Project was determined to have no impact with regards to these criteria, which will not be discussed hereafter.

Substantial depletion of groundwater supplies or interference with groundwater recharge resulting in a net deficit of aquifer volume or lowering of level of the local groundwater table.

No Impact. Construction of steel lattice structures for the new transmission line would require concrete foundations with footings averaging a depth of 20 feet, depending on soil conditions, and construction of TSPs would require foundations from 15 feet to 30 feet deep, depending on soil conditions.

Aquifers in the BRRTP area are generally unconfined, and depths of water-bearing formations exceed the distance required for foundations and footings. While there is potential for groundwater to be encountered during auguring activities along certain segments, dewatering activities are unlikely to deplete groundwater supplies. Construction, operation, and maintenance of the Project will not interfere with groundwater recharge or otherwise lower the levels of local groundwater tables.

Placement of housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map.

No Impact. Construction of the transmission line and the new Haskell Canyon Switching Station, expansion of the Barren Ridge Switching Station, and reconductoring of the existing BR-RIN line does not involve the placement of housing within a 100-year flood hazard area.

Exposure of people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam.

No Impact. Although segments of the new 230 kV transmission line would be located adjacent to reservoirs, structures for the transmission line would be sited so that the line would either span the area of hazard (e.g., Castaic Lake), or be placed on a ridge above the dam (e.g., Bouquet Reservoir). Construction and operation of the Project would not cause or increase the likelihood of failure of a levee or dam that could result in flooding. As such, the Project would not expose people or structures to a significant risk of loss, injury, or death involving flooding resulting from the failure of a levee or dam.

7.0 IMPACT RESULTS

Project-related impacts were initially assessed without reference to GPs or MMs. Once initial impacts were determined using the methodology described in Section 6.0, GPs and MMs were recommended and applied to each impact to minimize potential impacts resulting from construction, operation, and maintenance of the BRRTP. A detailed table of impacts to water resources can be found in Appendix A.

7.1 SEGMENT A

Segment A is approximately 13 miles long, beginning at LADWPs Barren Ridge Switching Station near Pine Tree Canyon and travelling southeast near the base of the Barren Ridge and the Tehachapi Mountains toward the unincorporated community of Mojave.

Segment A crosses multiple intermittent streams, including Pine Tree Canyon Creek at mile marker 0.6, and Cache Creek at mile marker 10.5. A 100-year floodplain associated with Pine Tree Canyon is crossed from mile marker 0.6 to mile marker 1.1, and a second 100-year floodplain associated with Cache Creek is crossed from mile marker 9.8 to mile marker 10.6. Existing roads would be utilized for construction, operation, and maintenance activities (access level 1). Ground disturbance within Segment A would be limited to crushing or blading of vegetation as required for work areas and construction of foundations, footings, and tower structures.

Construction of Segment A would result in a temporary ground disturbance of 86.5 acres and a permanent ground disturbance of 10.6 acres.

Potential impacts resulting from construction, operation, and maintenance activities within Segment A include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, contribution of additional sources of polluted runoff, and the placement of tower structures within a 100-year floodplain.

Given the relatively low level of ground disturbance and the low angle of slope along the length of Segment A, these impacts were determined to be low. Implementation of MMs presented in Table 7-1 would further reduce impacts to a negligible level (see Appendix A for details on impact locations and applicable Mitigation Measures).

TABLE 7-1. MITIGATION MEASURES APPLICABLE TO SEGMENT A

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4
Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.	HYD-5, HYD-6

7.2 SEGMENT B

Segment B is approximately 27 miles long. It begins just north of the unincorporated community of Mojave and runs south to the Antelope Valley California Poppy Reserve. Segment B parallels LADWPs 230 kV BR-RIN transmission line and 500 kV PDCI transmission line. Three multi-circuit towers are proposed in the Willow Springs area.

Segment B crosses multiple unnamed intermittent streams flowing out of the Tehachapi Mountains, and three 100-year floodplains. The first floodplain is crossed from mile marker 0.0 to 5.2. The second 100-year floodplain is crossed from mile marker 11.4 to 20.4. Both floodplains are in the Antelope Valley plain, and are associated with the many intermittent streams that flow out of the Tehachapi Mountains. The third floodplain is crossed from mile marker 23.8 to 24.2. This floodplain is associated with intermittent streams that flow out of Broad Canyon and the Fairmont and Antelope Buttes. Partially hydric soils have been mapped within Segment B from mile marker 15.7 to 24.7, mile marker 24.8 to 25.8, and mile marker 26.2 to 26.4.

Existing roads would be utilized for construction, operation, and maintenance activities within Segment B (access level 1). Ground disturbance within Segment B would be limited to crushing or blading of vegetation as required for work areas and construction of foundations, footings, and tower structures.

Construction of Segment B would result in a temporary ground disturbance of 172.3 acres and a permanent ground disturbance of 21.2 acres.

Potential impacts resulting from construction, operation, and maintenance activities within Segment B include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, contribution of additional sources of polluted runoff, and the placement of tower structures within a 100-year floodplain.

Given the relatively low level of ground disturbance and the low angle of slope along the length of Segment B, these impacts were determined to be low. Implementation of MMs presented in Table 7-2 would further reduce impacts to a negligible level (see Appendix A for details on impact locations and applicable Mitigation Measures).

TABLE 7-2. MITIGATION MEASURES APPLICABLE TO SEGMENT B

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4
Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.	HYD-5, HYD-6

7.3 SEGMENT C

Segment C is approximately 22 miles long, beginning just north of the unincorporated community of Mojave (at the junction of Segments A and B) and travelling southwest toward the 230 kV Magunden –

Vincent Transmission Line owned by SCE. Segment C parallels the First Los Angeles Aqueduct for approximately 18 miles, from mile marker 0.0 to 18.1, just north of Cottonwood Creek.

Segment C crosses multiple perennial and intermittent streams that flow out of the Tehachapi Mountains, including Oak Creek at mile marker 8.9 and Cottonwood Creek at mile marker 20.2. Segment C crosses two broad 100-year floodplains; the first floodplain is crossed from mile marker 0.0 to 5.8, and the second is crossed from mile marker 8.6 to 20.6. Both floodplains are associated with perennial and intermittent streams flowing out of the Tehachapi Mountains, and are the same broad floodplains crossed by Segment C. Three areas of partially hydric soils are mapped within Segment C. The first area is mapped from mile marker 18.5 to 19.7, the second from mile marker 20.1 to 20.4, and the third from mile marker 20.6 to 20.8.

Existing roads would be utilized for construction and maintenance along the greater portion of Segment C; however, many of these existing roads may require widening, vegetation clearing, or additional maintenance (access level 2), resulting in approximately 1.0 to 1.5 acres of permanent disturbance per mile of transmission line. Approximately 4.4 miles of new roads would be constructed within Segment C, resulting in an estimated 1.9 to 4.8 acres of permanent disturbance per mile of transmission line where new roads are constructed (access level 3). Ground disturbance within Segment C would also include crushing or blading of vegetation as required for work areas and construction of foundations, footings, and tower structures.

Construction of Segment C would result in a temporary ground disturbance of 141.1 acres, and permanent ground disturbance would range from 38.3 acres to 72.1 acres (average permanent ground disturbance 55.2 acres).

Potential impacts resulting from construction, operation, and maintenance activities within Segment C include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, contribution of additional sources of polluted runoff, and the placement of tower structures within a 100-year floodplain.

Without mitigation, impacts resulting from construction of new roads would be moderate; however, implementation of the MMs presented in Table 7-3 below would minimize these impacts to a low level. Elsewhere within Segment C, ground disturbance resulting from upgrading existing roads and from work areas required for construction would result in low impacts without mitigation. Implementation of MMs would minimize these impacts to a negligible level (see Appendix A for details on impact locations and applicable Mitigation Measures).

TABLE 7-3. MITIGATION MEASURES APPLICABLE TO SEGMENT C

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4
Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.	HYD-5, HYD-6

7.4 SEGMENT D

Segment D is approximately 48 miles long. It generally parallels the Los Angeles Aqueduct beginning just south of Cottonwood Creek and travelling south to the California Aqueduct, where it turns west to the Interstate 5 utility corridor. From there, Segment D heads southeast along the existing Castaic – Rinaldi corridor owned by LADWP to the proposed Haskell Canyon Switching Station.

Segment D crosses multiple perennial and intermittent streams, including Cow Spring Canyon Creek, Horsecamp Canyon Creek, Tentrock Canyon Creek, West Fork Liebre Gulch, Liebre Gulch, Trough Canyon Creek, Posey Canyon Creek, Big Oak Flats, Canton Canyon Creek, Grasshopper Canyon Creek, Eltter Canyon Creek, Charlie Canyon Creek, San Francisquito Canyon Creek, and Dry Canyon Creek, all of which flow out of the San Gabriel Mountains. Segment D also crosses multiple unnamed perennial and intermittent streams that flow from both the Tehachapi Mountains and the San Gabriel Mountains.

From mile marker 10.6 to 11.6, Segment D crosses a 100-year floodplain associated with streams flowing out of the Tehachapi Mountains. Another 100-year floodplain, associated with flows from Pine Canyon, is crossed between mile marker 13.6 and 13.9. From mile marker 41.6 to 41.8, Segment D crosses the 100-year floodplain associated with the spillway of Castaic Lake Dam, and the 100-year floodplain associated with San Francisquito Creek is crossed from mile marker 46.1 to 46.3.

Partially hydric soils are mapped in multiple scattered locations within Segment D. The largest mapped units of partially hydric soils are crossed between mile marker 20.4 and 23.3, and between mile marker 37.2 and 43.3.

Segment D generally parallels the Los Angeles Aqueduct as far as West Avenue G, crossing a flume at mile marker 10.8, then crossing the aqueduct at mile marker 9.4. At Avenue G, Segment D turns west and parallels the California Aqueduct flume from the Tehachapi Forebay, crossing the flume at mile marker 13.6. Segment D crosses the West Branch California Aqueduct tunnel at mile marker 33.5, and the Los Angeles Aqueduct tunnel at mile marker 46.9.

One groundwater well is crossed by Segment D. This well, #08N16W04N001S, is located under the proposed centerline at mile marker 11.1. DWR records for this well do not go beyond 1962, and the current status of this well is unknown.

As Segment D leaves the Antelope Valley it crosses the San Andreas Rift Zone SEA. This SEA would be spanned from mile marker 14.7 to 22.5. Toward the end point of Segment D, from mile marker 46.1 to 46.4, Segment D crosses the Santa Clara River SEA. As Segment D crosses into the Angeles National Forest it crosses RCAs associated with West Fork Liebre Gulch, Liebre Gulch, Trough Canyon, Posey Canyon, Big Oak Flats, Canton Canyon, Eltter Canyon, Charlie Canyon, Dry Canyon, and various unnamed streams.

At the request of the USFS, a RUSLE analysis to estimate the rate of erosion resulting from construction and operation of the Project was performed for the portion of Segment D that crosses the Angeles National Forest. Segment D would affect eight subwatersheds: Gorman Creek, Liebre Gulch-Piru Creek, Lake Piru-Piru Creek, Middle Castaic Creek, Upper Castaic Creek, Lower Bouquet Creek, Lower Castaic Creek, and San Francisquito Canyon. These watersheds have an average estimated baseline erosion rate of 48.15 tons/acres/year. Results of the RUSLE model predicted an average post-construction erosion increase of 0.68 percent (48.43 tons/acre/year) over baseline for the affected subwatersheds. Of the eight subwatersheds, Liebre Gulch-Piru Creek would have the largest potential increase (2.26 percent) over baseline conditions from construction of Alternative 1 (please see Appendix B for details of the RUSLE analysis).

Existing roads (access level 1) would be used for construction, operation, and maintenance within the greater portion of the Antelope Valley, although some may require widening or vegetation clearing (access level 2). In some areas of relatively flat terrain, especially between mile marker 2.5 and 5.4, new roads would be required (access level 3).

Existing access and spur roads would be utilized to the maximum extent possible for construction, operation, and maintenance of Segment D within the Angeles National Forest; however, some sections of the Segment D corridor have no access roads, and new roads would have to be constructed. Terrain in these sections is mountainous, with ground slopes ranging from 10 percent (access level 4) to greater than 30 percent (access level 6). Potential for erosion increases with increased ground slope. New roads built on slopes of 20 percent to 30 percent (access level 4) can result in permanent disturbance of approximately 4.8 to 7.7 acres per mile of transmission line, new roads built on slopes of 20 percent to 30 percent (access level 5) can result in permanent disturbance of approximately 7.7 to 11.6 acres of permanent disturbance per mile of transmission line, and new roads built on slopes of greater than 30 percent (access level 6) can result in permanent disturbance of approximately 11.6 to 15.5 acres per mile of transmission line.

In the San Gabriel Mountains outside the boundaries of the Angeles National Forest, existing roads are available for use (access levels 1 and 2) except at mile marker 37.2, which would require a new access level 6 road; and at mile markers 39.2, 45.3, and 47.2, where new access level 4 roads would be required.

Along Segment D within the Angeles National Forest, where existing access is limited or where resources are very sensitive, helicopter construction would be utilized as a general mitigation measure to reduce the need for construction of new access roads for tower construction. This measure would minimize ground disturbance associated with crane pads, structure laydown areas, and the need for large construction vehicles and equipment. In certain areas of the ANF, new temporary access roads may be constructed for access to pulling and tensioning sites and staging areas. Acres of disturbance for helicopter construction have been estimated on a per mile basis for general analysis, and this estimated acreage has been utilized for overall ground disturbance calculations.

Construction of Segment D would result in temporary ground disturbance ranging from 348.0 acres to 371.9 acres (average temporary ground disturbance 360.0 acres), and permanent ground disturbance would range from 71.5 acres to 116.4 acres (average permanent ground disturbance 94.0 acres).

Potential impacts resulting from construction, operation, and maintenance activities within Segment D include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, contribution of additional sources of polluted runoff, placement of tower structures within a 100-year floodplain, and potential for damage from inundation by seismic seiche.

The level of magnitude of potential impacts resulting from the Project increases with slope, as discussed above. Within the relatively flat slopes of the Antelope Valley, unmitigated impacts range from low to moderate; as Segment D crosses into mountainous terrain, impact levels prior to mitigation range from low to high, depending on the resource (refer to Table 6.1). For example, the potential for erosion and related impacts is greatest on steep slopes; therefore, impact levels related to erosion would be higher than impact levels on relatively flat terrain.

Implementation of recommended MMs would reduce impact levels by one degree; i.e., high impacts would be mitigated to a moderate level, moderate impacts would be mitigated to a low level, and low impacts would be minimized to a negligible level (see Appendix A for details on impact locations and applicable Mitigation Measures).

TABLE 7-4. MITIGATION MEASURES APPLICABLE TO SEGMENT D

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2, HELICOPTER
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-HELICOPTER
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4
Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.	HYD-5, HYD-6
Result in or be subject to damage from inundation by seiche, tsunami, or mudflow.	HYD – 7

7.5 SEGMENT E

Segment E is approximately 11 miles long, beginning from just south of Cottonwood Creek and travelling southeast, crossing over the eastern edge of the Antelope Buttes toward the Antelope Valley California Poppy Reserve, ending just south of West Avenue G.

Segment E crosses multiple unnamed intermittent and ephemeral streams, two of which, at mile marker 7.8 and 8.1, are associated with a 100-year floodplain. Segment E crosses a broader 100-year floodplain from mile marker 1.6 to 4.2.

Partially hydric soils are mapped throughout the Antelope Valley. Segment E crosses partially hydric soils from mile marker 0.9 to 8.8, and again between mile marker 10.0 and 10.7.

Segment E crosses two SEAs: Joshua Tree Woodlands SEA is crossed from mile marker 5.8 to 6.9, and the San Andreas Rift Zone SEA is crossed between mile marker 7.7 and 10.2.

Existing roads would be utilized for construction and maintenance along Segment E; however, a portion of these existing roads may require widening, vegetation clearing, or additional maintenance (access level 2), resulting in approximately 1.0 to 1.5 acres of permanent disturbance per mile of transmission line.

Construction of Segment E would result in a temporary ground disturbance of 73.5 acres, and permanent ground disturbance would range from 10.4 acres to 12.6 acres (average permanent ground disturbance 11.5 acres).

Potential impacts resulting from construction, operation, and maintenance activities within Segment E include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, contribution of additional sources of polluted runoff, and the placement of tower structures within a 100-year floodplain.

Given the relatively low level of ground disturbance and the low angle of slope along the length of Segment E, these impacts were determined to be low. Implementation of MMs would further reduce impacts to a negligible level (see Appendix A for details on impact locations and applicable Mitigation Measures).

TABLE 7-5. MITIGATION MEASURES APPLICABLE TO SEGMENT E

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4
Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.	HYD-5, HYD-6

7.6 SEGMENT F

Segment F is the shortest corridor, measuring approximately four miles. For the purposes of this assessment, Segment F has been divided into two sub-corridors: F1 and F2.

Segment F1 begins at the Antelope Valley California Poppy Reserve and runs southeast 0.08 mile to 115th Street. Although no water resources occur within this segment, potential indirect impacts resulting from construction of the transmission line include impacts to water quality. Existing roads would be used for construction, operation, and maintenance activities along Segment F1. Given the relatively low level of ground disturbance and the low angle of slope along the length of Segment F1, these impacts were determined to be low. Implementation of MMs would further reduce impacts to a negligible level.

Segment F2 begins at 115th Street and continues southeast toward Antelope Substation, owned by SCE. Between mile marker 0.5 and 0.7, Segment F2 crosses an intermittent stream that flows out of Myrick Canyon. This stream has an associated 100-year floodplain, which is crossed from mile marker 0.2 to 0.8. This is the only 100-year floodplain that is crossed by the Segment F2 corridor. Between mile marker 2.0 and 2.2, Segment F2 crosses a second intermittent stream that flows out of the foothills to the southwest.

Segment F2 crosses two mapped areas of partially hydric soils. The first area is crossed from mile marker 0.2 and 0.3, roughly corresponding with the 100-year floodplain. The second area is crossed between mile marker 1.1 and 2.5. No other water resource features are crossed by Segment F2.

Existing roads would be utilized for construction and maintenance along Segment F2; however, a portion of these existing roads may require widening, vegetation clearing, or additional maintenance (access level 2) resulting in approximately 1.0 to 1.5 acres of permanent disturbance per mile of transmission line.

Construction of Segment F1 would result in a temporary ground disturbance of 5.9 acres, and a permanent ground disturbance of 0.7 acres.

Construction of Segment F2 would result in a temporary ground disturbance of 18.2 acres, and permanent ground disturbance would range from 3.4 acres to 5.4 acres (average permanent ground disturbance 4.4 acres).

Potential impacts resulting from construction, operation, and maintenance activities within Segment F2 include impacts to water quality, creation of erosion or siltation on- or off-site, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, increase in the rate or amount of surface water runoff resulting in flooding, contribution of additional sources of polluted runoff, and the placement of tower structures within a 100-year floodplain.

Given the relatively low level of ground disturbance and the low angle of slope along the length of Segment F2, these impacts were determined to be low. Implementation of MMs would further reduce impacts to a negligible level (see Appendix A for details on impact locations and applicable Mitigation Measures).

TABLE 7-6. MITIGATION MEASURES APPLICABLE TO SEGMENTS F1 AND F2

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4
Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.	HYD-5, HYD-6

7.7 SEGMENTS G AND 2A

Segment G is approximately 21 miles long, 13 miles of which are within the Angeles National Forest. This segment begins at the Antelope Valley California Poppy Reserve and runs south/southwest to the proposed new Haskell Canyon Switching Station. The BRRTP would utilize existing four-circuit structures for approximately two miles, from towers 234-3 to 236-2. The multi-circuit mitigation is proposed in select areas (e.g., Elizabeth Lake, Green Valley) along Segment G where land use and visual resource impacts may be significant.

A localized alternative segment, Segment 2a, would route Segment G around the community of Green Valley. Segment 2a is approximately seven miles in length, and would replace an approximately five-mile section of Segment G that would pass through Green Valley. Segment 2a would divert from Segment G at mile marker 6.2 and turn west around Grass Mountain, then head south along the western side of Portal Canyon, and rejoin the original Segment G alignment at mile marker 11.

Segment G crosses multiple perennial and intermittent streams, including San Francisquito Canyon Creek, an eligible Wild and Scenic River. San Francisquito Canyon Creek is crossed between mile marker 12.1 and 12.4. San Francisquito Canyon Creek has an associated 100-year floodplain which is crossed by this same span. Segment G crosses a 100-year floodplain from mile marker 1.2 to 1.6, associated with a stream flowing out of Myrick Canyon to the southwest. Three additional 100-year floodplains are crossed. Between mile marker 5.4 and 5.6, the corridor crosses the 100-year floodplain associated with an unnamed stream flowing on the south slope of Portal Ridge into Elizabeth Lake; another 100-year floodplain, associated with Portal Canyon, is crossed between mile markers 10.3 and 10.5; a final 100-year floodplain, associated with Bee Canyon Creek, is crossed between mile markers 13.5 and 13.7.

Some areas of partially hydric soils have been mapped within the Segment G corridor between mile marker 1.0 and 6.6; however, beyond mile marker 6.6, the NRCS has no hydric soil information available and the existence of hydric soils within this portion of Segment G is unknown. Mapped areas of partially hydric soils are crossed by Segment G from mile marker 1.0 to 1.9, mile marker 3.4 to 3.8, and mile marker 4.9 to 6.5.

Segment G crosses the California Aqueduct at mile marker 3.9. The Bouquet Pipeline of the Los Angeles Aqueduct, which leads from the main stem of the aqueduct into Bouquet Reservoir, is crossed at mile marker 11.7, and the Los Angeles Aqueduct tunnel is crossed from mile marker 12.4 to 12.8.

One NWI wetland is mapped within the Segment G corridor. From mile marker 5.4 to 5.6, Segment G crosses a PEM wetland.

Segment G crosses the San Andreas Rift Zone SEA from mile marker 3.9 to 5.8, and the Santa Clara River SEA is crossed from mile marker 10.3 to 10.5. The segment corridor also crosses multiple RCAs between mile marker 6.3 and 20.8. The greatest expanse of RCA is crossed between mile marker 15.1 and 16.8; this RCA is associated with San Francisquito Canyon Creek and several of its tributaries.

At the request of the USFS, a RUSLE analysis was performed for the portion of Segment G that crosses the Angeles National Forest. Segment G would affect three subwatersheds: Elizabeth Lake, Lower Bouquet Creek, and San Francisquito Canyon. Results of the RUSLE model predicted an average post-construction erosion increase of 1.18 percent (44.43 tons/acre/year) over baseline for the affected subwatersheds. Of the three affected subwatersheds, Elizabeth Lake would have the largest potential increase (1.59 percent) over baseline (please see Appendix B for details of the RUSLE analysis).

Existing roads would be utilized for construction and maintenance along Segment G; however, most of these existing roads may require widening, vegetation clearing, or additional maintenance (access level 2), resulting in approximately 1.0 to 1.5 acres of permanent disturbance per mile of transmission line. Of those roads that may require upgrading, 0.2 mile occurs within the PEM wetland and 8.2 miles are within RCAs. Access level 2 roads within these areas would result in permanent disturbance of approximately 8.2 to 12.3 acres within Segment G.

Construction of Segment G would result in temporary ground disturbance ranging from 140.9 acres to 142.1 acres (average temporary ground disturbance 141.5 acres), and permanent ground disturbance would range from 25.9 acres to 39.7 acres (average permanent ground disturbance 32.8 acres).

Potential impacts resulting from construction, operation, and maintenance activities within Segment G include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, contribution of additional sources of polluted runoff, removal, filling, or hydrological interruption of wetlands, placement of tower structures within a 100-year floodplain, and potential for damage from inundation by seismic seiche.

The level of magnitude of potential impacts resulting from the Project increases with increased sensitivity of the resources impacted, as discussed in Section 6.1. Impact levels also increase with slope; for example, the potential for erosion and related impacts is greatest on steep slopes, therefore impact levels related to erosion would be higher than impact levels on relatively flat terrain.

Within the Segment G corridor, unmitigated impacts range from low to moderate, depending on the resource affected (refer to Table 6.1). With implementation of recommended MMs, moderate impacts would be reduced to a low level, and low impacts would be reduced to a negligible level (see Appendix A for details on impact locations and applicable Mitigation Measures).

Segment 2a closely parallels Burns Canyon, South Portal Canyon, and Munz Canyon, and crosses several unnamed intermittent streams. Two of these streams are tributary to South Portal Canyon, and one is tributary to San Francisquito Canyon. Several Riparian Conservation Areas, associated with Munz Canyon creek and several unnamed streams, are crossed from mile marker 1.1 to 1.5, from 1.6 to 2.3, from 2.9 to 4.0, from 5.1 to 5.5, and from 6.1 to 6.6.

Partially hydric soils are crossed from mile marker 1.1 to 1.2; however, beyond mile marker 1.2 the NRCS has no hydric soil information available and the existence of hydric soils within the remainder of Segment 2a is unknown. No NWI wetlands or 100-year floodplains are crossed by Segment 2a.

Segment 2a crosses the Los Angeles Aqueduct tunnel from mile marker 3.6 to 3.8, and again from mile marker 5.1 to 5.2.

Existing roads would be utilized for construction and maintenance along most of Segment 2a; however, most of these existing roads may require widening, vegetation clearing, or additional maintenance (access level 2), resulting in approximately 1.0 to 1.5 acres of permanent disturbance per mile of transmission line. Of those roads that may require upgrading, 0.9 mile are within RCAs. Access level 2 roads within these areas would result in permanent disturbance of approximately 1.6 to 2.1 acres within Segment 2a.

Approximately 0.5 mile of new (access level 4) roads would have to be constructed from mile marker 5.2 to 5.4 and 6.1 to 6.3. At mile marker 0.9, 5.1, and from mile marker 5.4 to 5.6 new access level 5 roads would be required, and new access level 6 roads would be constructed from mile marker 4.8 to 5.1, and 5.6 to 6.0.

Along Segment 2a within the Angeles National Forest, where existing access is limited or where resources are very sensitive, helicopter construction would be utilized as a general mitigation measure to reduce the need for construction of new access roads for tower construction. This measure would minimize ground disturbance associated with crane pads, structure laydown areas, and the need for large construction vehicles and equipment. In certain areas of the ANF, new temporary access roads may be constructed for access to pulling and tensioning sites and staging areas. Acres of disturbance for helicopter construction have been estimated on a per mile basis for general analysis, and this estimated acreage has been utilized for overall ground disturbance calculations.

Construction of Segment 2a would result in temporary ground disturbance ranging from 130.8 acres to 159.3 acres (average temporary disturbance 145.1 acres), and permanent ground disturbance would range from 28.9 acres to 44.2 acres (average permanent ground disturbance 36.5 acres).

Potential impacts resulting from construction, operation, and maintenance activities within Segment 2a include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, and contribution of additional sources of polluted runoff.

The level of magnitude of potential impacts resulting from the Project increases with increased sensitivity of the resources impacted, as discussed in Section 6.1. Impact levels also increase with slope; for example, the potential for erosion and related impacts is greatest on steep slopes, therefore impact levels related to erosion would be higher than impact levels on relatively flat terrain.

Within the Segment 2a corridor, unmitigated impacts range from low to high, depending on the resource affected (refer to Table 6.1). With implementation of recommended MMs, high impacts would be reduced to moderate, moderate impacts would be reduced to a low level, and low impacts would be reduced to a negligible level (see Appendix A for details on impact locations and applicable Mitigation Measures).

TABLE 7-7. MITIGATION MEASURES APPLICABLE TO SEGMENTS G AND 2A

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2, HELICOPTER
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2, HELICOPTER
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4
Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.	HYD-5, HYD-6

7.8 SEGMENT H

Segment H is approximately 20 miles long, and would parallel SCE's Antelope – Pardee transmission line, currently under construction. Segment H would begin at Antelope Substation, owned by SCE, and run south/southwest to the proposed Haskell Canyon Switching Station. From the northern border of the Angeles National Forest, near mile marker 2.5, to the southern border near mile marker 16.5, tower structures would be constructed by helicopter.

For the purpose of this analysis, Segment H has been divided into two sub-corridors: Segment H1 and Segment H2.

Segment H1 begins at Antelope Substation and travels southwest approximately 2.7 miles. This segment crosses several unnamed intermittent streams that carry stormwater away from the California Aqueduct. Segment H1 crosses the aqueduct at mile marker 2.2, where it also crosses into the San Andreas Rift Zone SEA. At mile marker 2.1, Segment H1 crosses a PUB wetland; this wetland, to which the NWI has given the modifier *Fx* (semi-permanently flooded, excavated), is an ornamental pond.

Existing roads would be utilized for construction and maintenance along Segment H1; however, most of these existing roads may require widening, vegetation clearing, or additional maintenance (access level 2), resulting in approximately 1.0 to 1.5 acres of permanent disturbance per mile of transmission line.

Construction of Segment H1 would result in a temporary ground disturbance of 18.2 acres, and permanent ground disturbance would range from 4.9 acres to 9.2 acres (average permanent ground disturbance 7.1 acres).

Potential impacts resulting from construction, operation, and maintenance activities within Segment H1 include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, and contribution of additional sources of polluted runoff.

Given the relatively low level of ground disturbance and the low angle of slope along the length of Segment H1, these impacts were determined to be low. Implementation of MMs would further reduce impacts to a negligible level.

Segment H2 begins south of the California Aqueduct near Power Line Road, and travels southwest approximately 17.1 miles. This corridor crosses multiple perennial and intermittent streams, including Bouquet Canyon Creek. Segment H2 crosses one 100-year floodplain from mile marker 1.7 to 1.9. This floodplain is associated with an unnamed stream crossed at mile marker 1.0, as well as with a PEM wetland at mile marker 1.7. A second PEM wetland is mapped at mile marker 1.0, and a PFO wetland is mapped at mile marker 5.3.

Some areas of partially hydric soils have been mapped within the Segment H2 corridor between mile marker 1.0 and 1.8, mile marker 15.6 and 15.8, mile marker 16.1 and 16.3, and mile marker 16.6 and 16.8; however, within most of the Segment H2 corridor, the NRCS has no hydric soil information available and the existence of hydric soils within the greater portion of Segment H2 is unknown.

RCAs occur throughout the Segment H2 corridor. The largest contiguous expanse of RCA is crossed from mile marker 13.2 to 14.6, with a slightly smaller expanse crossed from mile marker 15.0 to 15.8. These RCAs are associated with unnamed streams tributary to Bouquet Canyon Creek and Haskell Canyon Creek.

Bouquet Reservoir is located west and north of Segment H2 between mile marker 5.0 and 7.5.

Existing roads would be utilized for construction and maintenance along Segment H2 from mile marker 0.0 to 2.5; however, most of these existing roads may require widening, vegetation clearing, or additional maintenance (access level 2), resulting in approximately 1.0 to 1.5 acres of permanent disturbance per mile of transmission line. Both PEM wetlands would be crossed by access level 2 roads, and 1.6 miles of the corridor requiring access level 2 roads are within the San Andreas Rift SEA. Access level 2 roads within these areas would result in permanent disturbance of approximately 8.2 to 12.3 acres within Segment H2.

Segment H2 crosses the Angeles National Forest from mile marker 2.5 to 17.1. Within the boundaries of the Forest, tower structures would be constructed by helicopter, and no new roads would be constructed. While construction by helicopter avoids impacts related to road construction or upgrading, potential exists for impacts related to construction of structure foundations. These potential impacts are the same as potential impacts for road construction or upgrading.

Construction of Segment H2 would result in temporary ground disturbance ranging from 92.2 acres to 105.3 acres (average temporary disturbance 98.7 acres), and permanent ground disturbance would range from 17.1 acres to 29.2 acres (average permanent ground disturbance 23.2 acres).

Potential impacts resulting from construction, operation, and maintenance activities within Segment H2 include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, contribution of additional sources of polluted runoff, removal, filling, or hydrological interruption of wetlands, placement of tower structures within a 100-year floodplain, and potential for damage from inundation by seismic seiche.

The level of magnitude of potential impacts resulting from the Project increases with increased sensitivity of the resources impacted, as discussed in Section 6.1. Impact levels also increase with slope; for example, the potential for erosion and related impacts is greatest on steep slopes; therefore, impact levels related to erosion would be higher than impact levels on relatively flat terrain.

Within the Segment H2 corridor, unmitigated impacts range from low to high, depending on the resource affected (refer to Table 6.1) and the ground slope. With implementation of recommended MMs, high impacts would be reduced to a moderate level, moderate impacts would be reduced to a low level, and low impacts would be reduced to a negligible level (see Appendix A for details on impact locations and applicable Mitigation Measures).

TABLE 7-8. MITIGATION MEASURES APPLICABLE TO SEGMENT H1 AND H2

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2, HELICOPTER
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2, HELICOPTER
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4
Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.	HYD – 1
Result in or be subject to damage from inundation by seiche, tsunami, or mudflow.	HYD – 7

7.8.1 115th Street Modification

The 115th Street Modification was proposed as an alternative to Segment H1 to avoid impacts to residents in the Antelope Substation neighborhood. The Modification begins at the Antelope Valley California Poppy Reserve and parallels 115th Street south to the California Aqueduct.

The 115th Street Modification crosses multiple unnamed intermittent streams that carry stormwater away from the California Aqueduct. One 100-year floodplain, associated with the first two unnamed streams, is crossed from mile marker 0.3 to 0.5.

The Modification crosses the aqueduct at mile marker 4.0, where it also crosses into the San Andreas Rift Zone SEA. Mapped areas of partially hydric soils are crossed by the Modification. The broadest expanse of partially hydric soils is crossed between mile marker 0.2 and 2.0; other areas are crossed between mile marker 3.1 and 3.3, and again between mile marker 3.7 and 4.0.

One groundwater well is crossed by the Modification. This well, #07N14W14F001S, is located under the proposed centerline just south of Avenue I. DWR records indicate this well went dry in 1962, and is not currently active.

Existing roads would be utilized for construction and maintenance along the 115th Street Modification; however, most of these existing roads may require widening, vegetation clearing, or additional maintenance (access level 2), resulting in approximately 1.0 to 1.5 acres of permanent disturbance per mile of transmission line. Some portions of the Modification would require new roads to be constructed. Access level 3 roads would be required at mile marker 1.1; from mile marker 1.5 to 1.7, where the Modification crosses an unnamed stream; from mile marker 2.0 to 2.2, where the Modification crosses another unnamed stream; and again at mile marker 4.5, where the Modification crosses another unnamed stream. An access level 4 road would be required at mile marker 4.4, which is another stream crossing. The latter two access roads are within the San Andreas Rift Zone.

Construction of the 115th Street Modification would result in a temporary ground disturbance ranging from 33.0 acres to 33.8 acres (average temporary disturbance 33.4 acres), and permanent ground disturbance would range from 8.6 acres to 15.3 acres (average permanent ground disturbance 12.0 acres).

Potential impacts resulting from construction, operation, and maintenance activities within the 115th Street Modification include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, contribution of additional sources of polluted runoff, and placement of tower structures within a 100-year floodplain.

The level of magnitude of potential impacts resulting from the Project increases with increased ground slope; for example, the potential for erosion and related impacts is greatest on steep slopes; therefore, impact levels related to erosion would be higher than impact levels on relatively flat terrain.

Within the 115th Street Modification corridor, unmitigated impacts range from low to high, depending on road access level and slope. With implementation of recommended MMs, high impacts would be reduced to a moderate level, moderate impacts would be reduced to a low level, and low impacts would be reduced to a negligible level (see Appendix A for details on impact locations and applicable Mitigation Measures).

TABLE 7-9. MITIGATION MEASURES APPLICABLE TO THE 115TH STREET MODIFICATION

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2, HELICOPTER
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2, HELICOPTER
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4
Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.	HYD-5, HYD-6

7.9 SEGMENT I

Segment I is approximately 32 miles long. It begins at Antelope Substation and travels southeast toward Palmdale, paralleling the Midway – Vincent 500 kV high voltage transmission line, the Antelope – Vincent 230 kV transmission line, and the Antelope – Mesa 230 kV transmission line, all owned by SCE. At LADWPs existing 500 kV Victorville – Rinaldi transmission line and Adelanto – Rinaldi 230 kV transmission line, Segment I turns west/southwest to Haskell Canyon.

Segment I crosses or parallels multiple perennial and intermittent streams, including Amargosa Creek from mile marker 8.2 to 8.4, Anaverde Creek at mile marker 10.4, 12.9, and 13.5, Mint Canyon at mile marker 23.0, Vasquez Canyon Creek from mile marker 26.5 to 26.7, Bouquet Canyon from mile marker 28.7 to 28.9, and Haskell Canyon from mile marker 31.1 to 31.7. Multiple 100-year floodplains are crossed, including those associated with Amargosa Creek, from mile marker 8.2 to 8.5; Mint Canyon Creek, from mile marker 23.3 to 23.5; Vasquez Canyon Creek, from mile marker 26.5 to 26.7; and Bouquet Canyon Creek, from mile marker 28.6 to 28.9; and Haskell Canyon Creek, from mile marker 31.1 to 31.7.

Broad expanses of partially hydric soils are mapped throughout the Segment I corridor. The first is crossed from mile marker 3.0 to .04. The second is between mile marker 7.3 to 11.1, and is partially within the San Andreas Rift Zone SEA. Another expanse is crossed from mile marker 12.4 to 17.0, an area also crossed by multiple perennial and intermittent streams, including Anaverde Creek. A third expanse is mapped along Bouquet Canyon from mile marker 28.6 to 29.7. Additional expanses of partially hydric soils are mapped in association with streams in Mint Canyon, Vasquez Canyon, and Haskell Canyon, as well as several unnamed intermittent streams.

Segment I crosses the California Aqueduct at mile marker 5.0.

As mentioned above, Segment I crosses into the San Andreas Rift Zone SEA from mile marker 4.9 to 9.2. From mile marker 27.3 to 27.7, Segment I also crosses the Cruzan Mesa Vernal Pools SEA. This 0.4-mile span of the corridor crosses through the northernmost section of this SEA, but does not cross vernal pools; in fact, no NWI wetlands are mapped within the Segment I corridor.

At the request of the USFS, a RUSLE analysis was performed for the portion of Segment I that crosses the Angeles National Forest. Segment I would affect three subwatersheds: Mint Canyon, Sand Canyon-Santa Clara River, and Aqua Dulce Canyon. Results of the RUSLE model predicted an average post-construction erosion increase of 1.35 percent (35.82 tons/acre/year) over baseline for the affected subwatersheds. Of the three affected subwatersheds, Agua Dulce Canyon would have the largest potential increase (2.04 percent) over baseline (please see Appendix B for details of the RUSLE analysis).

Existing roads would be utilized for construction and maintenance along most of Segment I; however, most of these existing roads may require widening, vegetation clearing, or additional maintenance (access level 2), resulting in approximately 1.0 to 1.5 acres of permanent disturbance per mile of transmission line. Access level 2 roads would be required along 4.3 miles of the of the corridor within the San Andreas Rift Zone SEA. Level 4 access roads would be required along mile marker 17.8 to 17.9. Level 5 access roads would be required from mile marker 12.2 to 12.3, 23.7 to 23.8, and 28.7 to 29.0. While water features are associated with only one of these roads (at mile marker 12.2), potential exists for downstream impacts resulting from erosion at each of these locations, given the steepness of the ground slope.

Construction of Segment I would result in a temporary ground disturbance ranging from 226.9 acres to 235.1 acres (average temporary disturbance 231.0 acres), and permanent ground disturbance would range from 54.6 acres to 95.9 acres (average permanent ground disturbance 75.2 acres).

Potential impacts resulting from construction, operation, and maintenance activities within Segment I include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, contribution of additional sources of polluted runoff, and placement of tower structures within a 100-year floodplain.

The level of magnitude of potential impacts resulting from the Project increases with increased sensitivity of the resources impacted, as discussed in Section 6.1. Impact levels also increase with slope; for example, the potential for erosion and related impacts is greatest on steep slopes; therefore, impact levels related to erosion would be higher than impact levels on relatively flat terrain.

Within the Segment I corridor, unmitigated impacts would range from low to high, depending on the resource affected (refer to Table 6.1) and the ground slope. With implementation of recommended MMs, high impacts would be reduced to a moderate level, moderate impacts would be reduced to a low level, and low impacts would be reduced to a negligible level (see Appendix A for details on impact locations and applicable Mitigation Measures).

TABLE 7-10. MITIGATION MEASURES APPLICABLE TO SEGMENT I

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2, HELICOPTER
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2, HELICOPTER

Impact	Mitigation Measures
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4
Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.	HYD-5, HYD-6

7.10 NEW 230 KV CIRCUIT (SEGMENT J)

LADWP proposes to add approximately 12 miles of a new 230 kV transmission circuit onto the existing Castaic – Olive 230 kV transmission line structures (towers 1-1 through 12-1).

Addition of the new circuit would involve many of the same activities as construction of a new transmission line (surveying ROW, clearing or upgrading of existing access and spur roads, clearing of ROW, ground rod and conductor installation, and cleanup). It should be noted that the new double-circuit 230 kV structures proposed along Segment D would be located to the south of the existing tower structures on Segment J.

Segment J crosses multiple perennial and intermittent streams, including Dry Canyon Creek at mile marker 1.2, San Francisquito Canyon Creek at mile marker 1.9, Charlie Canyon at mile marker 3.4, and Bitter Canyon at mile marker 4.3. This segment also crosses the 100-year floodplain associated with San Francisquito Canyon Creek from mile marker 1.9 to 2.1, and a second 100-year floodplain from mile marker 6.4 to 6.6. This floodplain is associated with the spillway at Castaic Lake. Segment J also crosses the Los Angeles Aqueduct tunnel from mile marker 1.2 to 1.4.

Although existing roads would be used along Segment J, many of these roads would require upgrading (access level 2). Implementation of recommended MMs would reduce moderate impacts to a low level, and low impacts to a negligible level. Potential impacts resulting from circuit upgrade activities along Segment J include impacts to water quality, erosion or siltation on- or off-site, and damage from inundation by seismic seiche. When combined with the degree of ground slope, potential impacts within Segment J range from low to moderate.

TABLE 7-11. MITIGATION MEASURES APPLICABLE TO SEGMENT J

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2
Result in or be subject to damage from inundation by seiche, tsunami, or mudflow.	HYD – 7

7.11 RECONDUCTORING

Reconductoring of the existing BR-RIN transmission line would require many of the same activities as would construction of the new transmission line, including surveying of the ROW, upgrading of existing access and spur roads, clearing of the ROW, conductor installation, ground rod installation, and cleanup. Some of the towers would need to be modified or replaced, and foundations may need to be reinforced to carry the additional weight of the new, heavier conductor. All work would be restricted to the existing ROW.

The BR-RIN line is located along Segments A, B, G, and K. Potential impacts resulting from upgrading activities would be related to upgrading of existing roads and clearing of the ROW, and would include impacts to water quality, creation of erosion or siltation on- or off-site, increase in the rate or amount of surface water runoff resulting in flooding, creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of additional sources of polluted runoff, and placement of tower structures within a 100-year floodplain.

TABLE 7-12. MITIGATION MEASURES APPLICABLE TO RECONDUCTORING

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4
Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.	HYD-5, HYD-6

7.12 NEW SWITCHING STATION

The proposed new switching station in Haskell Canyon would be located on LADWP-owned property south of the Angeles National Forest. Construction of the new Haskell Canyon Switching Station would consist of clearing and upgrading of access roads, site grading and development, installation of electrical conduits, structures, and equipment.

The switching station yard would include a paved internal access road approximately 16 feet wide, along with a 100 foot by 100 foot gravel parking area, and would be enclosed by chain-link fencing with barbed-wire extension for security; this would create a station footprint of 2.7 acres. An additional 16.7 acres would be developed at the switching site to accommodate additional road and fencing. A total of 19.4 acres would be considered permanent impact.

An unnamed intermittent stream, tributary to Haskell Canyon Creek, flows across the northern portion of the property. This stream has no associated 100-year floodplain.

Potential impacts resulting from construction, operation, and maintenance of the new Haskell Canyon Switching Station would be impacts to water quality, creation of erosion or siltation on- or off-site, increase in rate or amount of surface water runoff resulting in flooding, and contribution of additional sources of polluted runoff.

Without mitigation, these impacts are determined to be moderate; with implementation of recommended MMs, the impacts would be reduced to low.

TABLE 7-13. MITIGATION MEASURES APPLICABLE TO NEW HASKELL CANYON SWITCHING STATION

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1

Impact	Mitigation Measures
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4

7.13 EXPANSION OF EXISTING BARREN RIDGE SWITCHING STATION

LADWP proposes to expand the existing Barren Ridge Switching Station to the east by 235 feet by 500 feet, creating a total station size of 485 feet by 500 feet (approximately 5.6 acres). The expansion area would include additional electrical structures for additional lines, a material staging area, an internal roadway, and a drainage area.

Although there are no water features on site, expansion of the Barren Ridge Switching Station would have potential to impact water resources off-site, including Pine Tree Canyon Creek which is approximately 0.5 mile south of the switching station.

Expansion activities of the existing switching station would be very similar to the construction of the new Haskell Canyon Switching Station, and would include clearing and upgrading of access roads, site grading and development, installation of electrical conduits, structures, and equipment. Potential impacts would include impacts to water quality, creation of erosion or siltation on- or off-site, increase in rate or amount of surface water runoff resulting in flooding, and contribution of additional sources of polluted runoff.

Without mitigation, these impacts are determined to be low; with implementation of recommended MMs, the impacts would be reduced to negligible.

TABLE 7-14. MITIGATION MEASURES APPLICABLE TO EXPANSION OF BARREN RIDGE SWITCHING STATION

Impact	Mitigation Measures
Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.	HYD – 1
Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.	HYD-1, HYD-2
Substantial alteration of existing drainage patterns or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.	HYD-1, HYD-2
Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial sources of polluted runoff.	HYD-3, HYD-4

8.0 ALTERNATIVES

NEPA and CEQA both require consideration of a reasonable range of alternatives to the Proposed Action that would feasibly attain most of the basic objectives of the Project, but avoid or substantially lessen any of the significant or adverse effects of the Project.

8.1 DEVELOPMENT OF ALTERNATIVES

A range of alternatives were identified through a siting analysis, the scoping process, and supplemental studies and consultations. A full discussion of alternatives development can be found in the Alternatives Development Report (POWER 2010).

The regional siting analysis identified nine routing opportunities (Segments A through I) for the new 230 kV transmission line between Barren Ridge Switching Station and the proposed Haskell Canyon Switching Station. Some of the routing opportunities or segments were adjusted or modified based on public input and preliminary environmental review, and preliminary electrical system studies. Each of the nine segments are discussed in detail, including impact analysis, in Section 7.0 of this report. Several of these segments were not used in the formation of alternatives as discussed below.

Segment E was recommended for elimination from analysis in the EIS/EIR. The Segment would require an additional 6.5 miles of transmission line in comparison to the Proposed Action and would not significantly reduce or avoid impacts to air quality, biological, cultural, visual, and water resources. Segment H was also recommended for elimination, due to increased impacts to air quality and noise, along with safety concerns, related to helicopter construction. Cumulative effects for the Project would also increase because of the further disturbance of revegetated and rehabilitated areas and potential for impacts from three transmission line projects in the same vicinity.

Eight routing opportunities (Segments A, B, C, D, F, G, 2a and I) were combined to create end-to-end routing alternatives for the proposed double-circuit 230 kV transmission line between Barren Ridge Switching Station and the proposed Haskell Canyon Switching Station. In addition to routing segments, each Alternative discussed within this section would include other Project components as discussed earlier within this report. These include the addition of a new circuit on existing towers between Castaic Power Plant and Haskell Canyon, reconductoring of the existing BR-RIN transmission line, construction of a new Haskell Canyon Switching Station, and expansion of the existing Barren Ridge Switching Station. Impact assessment and impact results for each of the other Project components listed above, and which are common to each of the Alternatives, are described in Section 7.0. Descriptions and impact assessment of the routing alternatives follow in the sections below.

8.2 ALTERNATIVES DESCRIPTION

The following alternatives were identified as a reasonable range of alternatives to the Project that would feasibly attain most of the basic objectives of the Project, but avoid or substantially lessen any of the significant or adverse effects of the Project.

8.2.1. Action Alternatives

In addition to a new double-circuit 230 kV transmission line between the Barren Ridge and Haskell Canyon switching stations, whose route would vary among the action Alternatives, the four action Alternatives would include the following common components: the expansion of the existing Barren Ridge Switching Station, construction of a new Haskell Canyon Switching Station, reconductoring of the existing 230 kV transmission line from the Barren Ridge Switching Station to Rinaldi Substation, and the addition of a new 230 kV circuit on existing towers between the Castaic Power Plant and Haskell Canyon Switching Station. Refer to Figure 8-1.

Alternative 1 (Segments A, C, and D)

The Alternative 1 230 kV double-circuit transmission line comprises the preliminary routing Segments A, C, and D, and is the longest Alternative, at 83 miles long. It would run from the Barren Ridge Switching Station to the unincorporated community of Mojave, while paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines. It would continue south-southwest to parallel the Los Angeles Aqueduct to Lancaster Road, where it would travel west to the I-5 utility corridor. It would then run southeast along LADWP's existing Castaic – Rinaldi corridor to the proposed Haskell Canyon Switching Station.

Helicopter Mitigation

Within the ANF where the terrain is steep and access is limited, the USFS would require that the new double-circuit 230 kV structures be constructed with the use of helicopters (such as the Hughes 500 or Bell 212, or Sikorsky Skycrane). Refer to Figure 8-2, the Identified Helicopter Mitigation Locations Map, which illustrates the identified locations for this mitigation. The use of helicopters for the construction of transmission tower structures would eliminate the need for new access roads to structure locations, and would therefore minimize land disturbance associated with crane pads, structure laydown areas, and the trucks and tractors used for delivery of structures to sites. However, the following site and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas, tower structure vegetation clearing, guard structures at major crossings, wire stringing sites, pullouts, and temporary access roads.

Alternative 2 (Segments A, B, and G) –LADWP's Proposed Action

Alternative 2, LADWP's Proposed Action, comprises Segments A, B, and G and is 61 miles long. It begins at the Barren Ridge Switching Station and runs south, paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines. It travels south from the unincorporated community of Mojave, California through the Antelope Valley and approximately one mile east of the Antelope Valley California Poppy Reserve before continuing onto National Forest System lands and ending at the proposed Haskell Canyon Switching Station. The entire route would remain within designated utility corridors and would parallel existing transmission lines. Refer to Section 1.2, Project Description, for a full description of this Alternative.

Alternative 2a (Segments A, B, G and 2a)

The 230 kV double-circuit transmission line in Alternative 2a comprises the preliminary routing Segments A, B, and G, but includes a re-route (Segment 2a) avoiding the unincorporated community of Green Valley. It is 63 miles long and would be very similar to the Proposed Action (Alternative 2), with 56 miles of the same alignment. Alternative 2a would begin at the Barren Ridge Switching Station and run south, paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI transmission lines. It would travel south from the unincorporated community of Mojave through the Antelope Valley and approximately one mile east of the Antelope Valley California Poppy Reserve before continuing onto NFS lands and ending at the proposed Haskell Canyon Switching Station. The route would remain within designated utility corridors and would parallel existing transmission lines, with the exception of the nearly seven miles that would be routed around the unincorporated community of Green Valley. Segment 2a would create a new utility corridor through the ANF. The re-route would rejoin Segment G south of the unincorporated community of Green Valley before continuing south and ending at the proposed Haskell Canyon Switching Station.

Three-Circuit Tower Mitigation

In areas where there are ROW expansion constraints and where LADWP has existing 230 kV transmission lines, LADWP is proposing to construct three-circuit towers to carry the existing BR-RIN circuit and two new BR-HC circuits. This would avoid various impacts including the acquisition of residential property in the unincorporated communities of Willow Springs (milepost 27.1 to 27.6) and Elizabeth Lake and Green Valley (milepost 44.6 to 46 and milepost 50.8 to 51.7). This mitigation would be utilized in the same areas that were identified for Three-Circuit Tower Mitigation for the Proposed Project, with the exception of approximately five miles through the unincorporated community of Green Valley, which would not utilize this mitigation. These areas are illustrated in 1-7, the Three-Circuit Tower Mitigation Map.

Helicopter Mitigation

Within the ANF where the terrain is steep and access is limited, the USFS would require that the new double-circuit 230 kV structures be constructed by the use of helicopter. Refer to Figure 8-2, Identified Helicopter Mitigation Locations, which illustrates the identified locations for this mitigation. The use of helicopters for the construction of transmission tower structures would eliminate the need for new access roads to structure locations, and would therefore minimize land disturbance associated with crane pads, structure laydown areas, and the trucks and tractors used for delivery of structures to sites. However, the following site and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas, tower structure vegetation clearing, guard structures at major crossings, wire stringing sites, pullouts, and temporary access roads. The estimated sizes of these auxiliary sites (temporary and permanent) and additional construction information is detailed above in the description of the Proposed Action (Alternative 2) and in Appendix C.

Alternative 3 (Segments A, B, F, and I)

The proposed 230 kV double-circuit transmission line in Alternative 3 comprises preliminary routing Segments A, B, F, and I. It is 76 miles long and would begin at the Barren Ridge Switching Station and run south, paralleling LADWP's existing 230 kV BR-RIN and 500 kV PDCI lines. It would travel south from the unincorporated community of Mojave through the Antelope Valley and approximately one mile east of the Antelope Valley California Poppy Reserve before continuing southeast past SCE's Antelope Substation. The route would then travel toward the city of Palmdale, parallel to SCE's existing high-voltage transmission lines. It would make a sharp turn to the south to parallel LADWP's existing Victorville – Rinaldi 500 kV and Adelanto – Rinaldi 230 kV transmission lines. This Alternative would then parallel these transmission lines west, crossing two miles of the ANF. The Alternative would then parallel LADWP's 500 kV PDCI line north to the proposed Haskell Canyon Switching Station.

Three-Circuit Tower Mitigation

In areas where there are ROW expansion constraints and where LADWP has existing 230 kV transmission lines, LADWP is proposing to construct three-circuit towers to carry the existing BR-RIN circuit and two new BR-HC circuits. This would avoid various impacts including the acquisition of residential property in the unincorporated communities of Willow Springs (milepost 27.1 to 27.6). Please refer to the small inset map on Figure 1-7.

Avenue L Re-route

To avoid acquisition of private property, a portion of Alternative 3 from mile marker 45.2 to 46.7 was moved to parallel a smaller distribution line south along 90th Street West and then east along West Avenue "L." Refer to Figure 8-3, Avenue L Re-route on Alternative 3.

8.2.2. No Action Alternative

Under the No Action Alternative, the construction of a new 230 kV transmission line, the addition of a new circuit on existing structures from Haskell Canyon to the Castaic Power Plant, the reconductoring of the existing BR-RIN transmission line, the construction of a new Haskell Canyon Switching Station, and the expansion of the existing Barren Ridge Switching Station would not occur. LADWP currently maintains an estimated 147 miles of existing access roads in the Project area, 97 of which are located within the ANF. Current, on-going operation and maintenance activates for existing facilities in the Project area would continue. The EIS/EIR must address the resulting environmental effects from taking no action and compare them to the effects of permitting the Proposed Action or an Alternative to the Proposed Action.

8.3 IMPACT RESULTS—ROUTING ALTERNATIVES

Alternative 1 (Segments A, C, and D)

Within the Angeles National Forest, Segment D crosses eight subwatersheds, with a combined area of 191,957 acres. Assuming no implementation of GPs, post-construction erosion resulting from Segment D would increase an average of 0.68 percent over baseline.

As discussed in Section 7.1 and 7.3, project-related impacts of Segments A and C would be negligible to low, after MMs are implemented. While both segments cross floodplains and multiple intermittent streams, the terrain crossed by Segments A and C is relatively flat, and existing roads would be utilized for the majority of construction within these segments. Ground disturbance would be low, limited to crushing or blading of vegetation where required for work areas. Existing roads would be used for construction within Segment A and within the majority of Segment C.

Impacts of Segment D, as discussed in Section 7.4, would range from high to low after implementation of MMs, depending on the terrain. Segment D crosses steep, rugged terrain (with slopes ranging from 10 percent to greater than 30 percent) where few roads exist that would be suitable for construction. Existing roads would have to be improved to allow for safe construction access and, where no roads exist, new roads would be constructed. Segment D crosses multiple intermittent streams, as well as the Santa Clara River SEA.

Construction of Alternative 1 would result in temporary ground disturbance ranging from 575.5 acres to 599.4 acres (average temporary disturbance 587.5 acres), and permanent ground disturbance would range from 120.5 acres to 199.2 acres Average permanent disturbance 159.8 acres).

Although impacts resulting from Segments A and C would be low to negligible, the higher level of impacts and greater area of impacts resulting from construction of Segment D would increase overall impacts resulting from construction of Alternative 1 to a moderate level.

Alternative 2 (Segments A, B, and G) –LADWP's Proposed Action

Within the Angeles National Forest, Segment G crosses three subwatersheds, with a combined area of 65,172 acres. Assuming no implementation of GPs, post-construction erosion resulting from Segment G would increase an average 1.18 percent over baseline, the smallest increase of the three alternative routes. As discussed in Section 7.1 and 7.2, project-related impacts of Segments A and B would be negligible to low, after MMs are implemented. While both segments cross floodplains and multiple intermittent streams, the terrain crossed by Segments A and B is relatively flat, and existing roads would be utilized for the majority of construction within these segments. Ground disturbance would be low, limited to crushing or blading of vegetation where required for work areas. Existing roads would be used for construction within Segment A and within the majority of Segment B.

Impacts resulting from construction of Segment G, as discussed in Section 7.7, would range from negligible to moderate with implementation of MMs. Segment G crosses multiple intermittent streams and floodplains, and one NWI wetland. Segment G crosses two SEAs, the San Andreas Rift Zone SEA and the Santa Clara River SEA. Terrain within Segment G ranges from relatively flat to slopes of over 30 percent. While Segment G is similar to Segment D in many ways, Segment G is less than half the length of Segment D, resulting in a lesser area of overall impact. In addition, existing roads would be used for construction throughout Segment G; while some roads would have to be improved to allow for safe access of construction vehicles, no new roads would be constructed.

Construction of Alternative 2 would result in a temporary ground disturbance ranging from 397.7 acres to 398.9 acres (average permanent disturbance 398.3 acres), and permanent ground disturbance would range from 57.0 acres to 69.8 acres (average permanent disturbance 63.4 acres).

The initial similarities to Segment D are counteracted by the shorter distance of Segment G and by the greater number of existing roads; thus, the overall impacts of Segment G are lower. In addition, Segment G would affect fewer subwatersheds within Angeles National Forest than would Segment D of Alternative 1, and predicted increase in erosion resulting from construction of Segment G is less than either Segment D or Segment I of Alternative 3. With the negligible to low impacts of Segments A and B taken into consideration, overall impacts of Alternative 2 would be low.

Alternative 2a (Segments A, B, G, and 2a)

Alternative 2a would substitute Segment 2a for the five-mile section of Segment G that crosses through the community of Green Valley. With this substitution, Alternative 2a would be approximately 22.5 miles in length.

Utilization of Segment 2a would increase project-related impacts due the necessity of constructing new access roads in areas where no roads exist. Approximately 1.6 miles of new roads would be constructed along Segment 2a, nearly half of which would be along slopes greater than 30 percent.

Construction of Alternative 2a would result in a temporary ground disturbance ranging from 404.7 acres to 409.1 acres (average temporary disturbance 406.9 acres), and permanent ground disturbance would range from 59.1 acres to 74.5 acres.

Segment 2a crosses five intermittent streams, whereas the corresponding section of Segment G crosses one stream. Segment 2a crosses 3.0 miles of Riparian Conservation Areas as opposed to 0.7 mile of RCAs crossed by its Segment G equivalent. Although impacts resulting from construction of Segment 2a would range from low to moderate, impacts from this segment would not significantly increase impacts resulting from Alternative 2a, which would be low.

Alternative 3 (Segments A, B, F, and I)

As discussed in Section 7.1 and 7.2, project-related impacts of Segments A and B would be negligible to low, after MMs are implemented. While both segments cross floodplains and multiple intermittent streams, the terrain crossed by Segments A and B is relatively flat, and existing roads would be utilized for the majority of construction within these segments. Ground disturbance would be low, limited to crushing or blading of vegetation where required for work areas. Existing roads would be used for construction within Segment A and within the majority of Segment B.

Within the Angeles National Forest, Segment I crosses three subwatersheds, with a combined area of 76,006 acres. Assuming no implementation of GPs, post-construction erosion resulting from Segment I would increase 1.35 percent over baseline, the greatest increase of the three alternative routes.

Segment I crosses relatively flat terrain, a 0.5-mile section of floodplain, and four intermittent streams, as discussed in Section 7.9. Existing roads would be used for construction within Segment I, and while some of these roads would have to be improved, overall ground disturbance within Segment I would be low. With implementation of MMs, project-related impacts within Segment I would be negligible.

Construction of Alternative 3 would result in a temporary ground disturbance ranging from 511.6 acres to 519.8 acres (average temporary disturbance 515.7 acres), and permanent ground disturbance would range from 91.1 acres to 135.0 acres (average permanent disturbance 113.1 acres).

Impacts resulting from construction of Segment I, as discussed in Section 7.9, would range from negligible to moderate, with implementation of MMs. Segment I crosses multiple intermittent streams and floodplains, and two SEAs, the San Andreas Rift Zone SEA and the Cruzan Mesa Vernal Pools SEA. Terrain within Segment I ranges from relatively flat to slopes of over 30 percent. While Segment I is similar to Segment G in many ways, Segment I is approximately 11 miles longer than Segment G, resulting in a greater area of overall impact. Existing roads would be used for construction throughout Segment I; while some roads would have to be improved to allow for safe access of construction vehicles, no new roads would be constructed.

While the project-related impacts resulting from Segments A, B, F, and I are low to negligible, the greater length of this Alternative would increase the quantity of project-related impacts. When quantity of impacts is considered, it is determined that overall impacts of Alternative 3 would be moderate.

8.3.2. No Action Alternative

With the No Action Alternative, no project-related ground disturbance would occur. While project-related construction and ground disturbance of the Proposed Action or any Alternative Action would result in negligible to moderate impacts to hydrology, water quality, and wetlands, the No Action Alternative would result in no such impacts. If the No Action Alternative is selected, hydrology, water quality, and wetlands within the Project area would remain in as they were when this inventory and analysis was conducted.

8.4 CUMULATIVE IMPACTS

8.4.1. Introduction

Cumulative effects are those effects that result from incremental impacts of the proposed action when added to other past, present and reasonably foreseeable future actions. Analysis of cumulative effects places project-specific impacts into a broader context that takes into account the full range of impacts of actions taking place over a given space and time. Cumulative effects may be considered a significant impact to the environment, as degradation of important resources may result from the combined, incremental effects of actions. Cumulative effects may result from individually minor or insignificant actions, which collectively may be considered significant as they accumulate over time and space from one or more actions or sources.

8.4.2. Impact Area

The alternative routes are located within two watersheds, the Antelope-Fremont Valleys watershed and the Santa Clara River watershed. Since the BRRTP and other projects in the region have potential to affect the entire watershed, as opposed to affecting only a smaller geographic area or subwatershed, these two watersheds define the impact area for this cumulative effects analysis.

8.4.3. Cumulative Projects List – Major Present and Reasonably Foreseeable Future Actions

The cumulative projects list is used to provide a general context for the cumulative effects. This list includes present and reasonably foreseeable future actions in the Project vicinity that have the potential to combine with the Proposed Action or Alternatives. While a distinct impact area for cumulative impacts and specific present and reasonably foreseeable actions is determined individually for each resource area, collectively, the projects listed below represent the major known and anticipated activities that may occur in the general Project area. The Cumulative Projects Map (Figure xx-1) illustrates the location of energy infrastructure and other major projects in reference to the Proposed Action and Alternatives.

As the project list comprises projects in various stages of planning and development, it is likely that some of these projects would be completed as currently proposed while others would not. To be conservative, the cumulative analysis assumes that all projects listed would be built and in operation during the operating lifetime of the proposed Project. The list was developed in consultation with the following agencies:

- USFS – Angeles National Forest (ANF)
- BLM – Ridgecrest Field Office
- BLM – Palm Springs Field Office
- United States Air Force – Edwards Air Force Base
- Kern County – Planning Department
- Los Angeles County – Department of Regional Planning
- City of California City
- City of Lancaster
- City of Palmdale
- City of Santa Clarita
- City of Los Angeles
- City of San Fernando
- LADWP

Energy Infrastructure Projects

Transmission Projects

Antelope Transmission Project – Construction of Southern California Edison's (SCE) proposed Antelope Transmission Project is underway and is proceeding in three sequential segments. Construction of Segments 1, 2 and 3A have been completed. Construction of Segment 3B, from Windhub Substation to and including Highwind Substation, has not started and no schedule has been developed by SCE (California Public Utilities – Current Projects).

Segment 1, Antelope – Pardee 500 kV Transmission Line, involved the construction of a new 25.6-mile transmission line between SCE's existing Antelope Substation in the city of Lancaster and SCE's existing Pardee Substation in Santa Clarita, with modifications to and/or expansion of the substations. The line was constructed in an existing SCE 66 kV transmission line right-of-way (ROW) for 23 miles, and within a new ROW for 18 miles. The line is initially energized to 220 kV to serve existing energy demand and can be upgraded to 500 kV to accommodate future needs.

Segment 2, Antelope – Vincent 500 kV Transmission Line, consists of a new 17.8 mile transmission line between the Antelope Substation and SCE's existing Vincent Substation near Acton. Similar to Segment 1, the line would initially be energized at 220 kV and upgraded to meet future needs.

Segment 3, Antelope – Tehachapi Transmission Line, consists of two phases. The first phase, 3A, would involve the construction of a new 26.1-mile 500 kV transmission line between the Antelope Substation and a proposed new substation in the vicinity of the unincorporated community of Mojave (Substation 1). Similar to Segments 1 and 2, this line would be initially energized at 220 kV and upgraded to meet future needs. The second phase, 3B, would involve the construction of a new 9.4-mile 220 kV transmission line from the proposed Substation 1 to a proposed new substation in the Monolith area (Substation 2).

Tehachapi Renewable Transmission Project (TRTP) – SCE is proposing to construct the TRTP, which would involve new and upgraded transmission infrastructure along 173 miles of new and existing rights-of-way, in southern Kern County, portions of Los Angeles County including the ANF, and the southwestern portion of San Bernardino County. Stated objectives for the project include providing the electrical facilities necessary to integrate levels of wind generation in excess of 700 MW and up to 4,500 MW in the Tehachapi Wind Resource Area (California Public Utilities – Current Projects).

The environmental review process for the project is currently underway. Construction began in April 2010 on approved sections. Project construction is estimated to be completed in 2015.

The project is composed of Segments 4 through 11, with Segments 4 through 8 and Segments 10 and 11 being transmission facilities, and Segment 9 being the addition and upgrade of substation facilities. Proposed transmission lines would be constructed primarily within existing rights-of-way. Major project components include:

- Constructing two new single-circuit 220 kV transmission lines within 4 miles of new ROW between the Cottonwood Substation and proposed Whirlwind Substation (Segment 4);
- Constructing a new single-circuit 500 kV transmission line within 16 miles of new ROW between the Antelope Substation and proposed Whirlwind Substation (Segment 4);
- Rebuilding 18 miles of the existing Antelope – Vincent and Antelope – Mesa 220 kV transmission lines to 500 kV standards within existing ROW between the Antelope and Vincent Substations (Segment 5);
- Rebuilding 27 miles of the existing Antelope – Mesa 220 kV transmission line and 5 miles of the existing Rio Hondo – Vincent 220 kV transmission line to 500 kV standards between the Vincent Substation and the southern boundary of the ANF (Segment 6);

- Rebuilding 16 miles of the existing Antelope – Mesa 220 kV transmission line to 500 kV standards between the southern boundary of the ANF and Mesa Substation (Segment 7);
- Rebuilding 33 miles of the existing Chino – Mesa 200 kV transmission line to 500 kV standards between a point 2 miles east of the Mesa Substation and the Mira Loma Substation (Segment 8);
- Rebuilding 7 miles of the existing Chino – Mira Loma No. 1 220 kV transmission line from single-circuit to double-circuit structures (Segment 8);
- Constructing a new 500/220 kV Whirlwind Substation 4 to 5 miles south of the Cottonwood Substation (Segment 9);
- Upgrading the existing Antelope, Vincent, Mesa, Gould, and Mira Loma Substations to accommodate new transmission line construction and system compensation elements (Segment 9);
- Constructing a new single-circuit 500 kV transmission line within 17 miles of new ROW between the Windhub Substation and proposed Whirlwind Substation (Segment 10);
- Rebuilding 19 miles of existing 220 kV transmission line to 500 kV standards in existing ROW between the Vincent and Gould Substations (Segment 11);
- Adding a new 220 kV circuit between the Mesa and Gould Substations on the vacant side of the existing Eagle Rock – Mesa 220 kV transmission line double circuit structures (Segment 11); and
- Installing associated telecommunications infrastructure.

Generation Projects

Numerous wind and solar generation projects are in various stages of planning and development within the Project vicinity. Projects considered include the projects currently undergoing environmental review or projects that have been recently approved. Table 8-1 below summarizes the major known projects and their current status as of April 2011 (County of Kern Environmental Documents and AV Solar Ranch One).

TABLE 8-1. PROPOSED GENERATION PROJECTS IN THE PROJECT VICINITY

Project Name	Project Type	Approximate Generation	Area (acres)	Location	Status
Alta East Wind Project	Wind	300 MW	3,660	Kern County	Application to Kern County deemed complete on Aug. 2010
Alta Wind Energy Center: Alta-Oak Creek Mojave Project	Wind Turbine	800 MW	9,175	Kern County	Approved by Kern County Dec. 2009
Antelope Valley Solar Project	Solar Photovoltaic	650 MW	5,698	Kern County	Draft EIR released April 2011
AV Solar Ranch One	Solar Photovoltaic	230 MW	21,000	Los Angeles County	Final EIR completed Aug. 2010
Avalon Wind Project	Wind	255 MW	10,000	Kern County	Application to Kern County deemed complete on July 2010
Beacon Solar Energy Project	Concentrated Solar	250 MW	2,012	Kern County	Application for Certification approved Aug. 2010
Catalina Renewable Energy Project	Wind Turbine & Solar Photovoltaic	350 MW	7,472	Kern County	Notice of Preparation for a Draft EIR filed Feb. 2011
Clearvista Wind Project	Wind Turbine	40 MW	226	Kern County	Draft EIR released Nov. 2010
Edwards Air Force Base Solar Project	Solar	500 MW	3,288	Kern County	Lease execution anticipated 2012
Lower West Wind Energy Project	Wind Turbine	14 MW	185	Kern County	Draft EIR released April 2011

Project Name	Project Type	Approximate Generation	Area (acres)	Location	Status
Monte Vista Solar Array	Solar Photovoltaic	126 MW	1,040	Kern County	Notice of Preparation for a Draft EIR filed March 2010
Morgan Hills Wind Project	Wind	230 MW	3,604	Kern County	Application submitted Nov. 2010
North Sky River Wind Project	Wind Turbine	326 MW	1,330	Kern County	Notice of Preparation for a Draft EIR filed Nov. 2010
Pacific Wind Energy Project	Wind Turbine	151 MW	8,300	Kern County	Approved by Kern County Oct. 2010
Pahnamid Wind Energy Project	Wind Turbine	411 MW	7,106	Kern County	Notice of Preparation for a Draft EIR filed April 2011
PdV Wind Energy Project	Wind Turbine	300 MW	5,820	Kern County	Approved by Kern County July 2008
Pine Canyon Wind Project	Wind Turbine	150 MW	12,000	Kern County	Preliminary planning
Pine Tree Solar Project	Solar Photovoltaic	10 MW	75	Kern County	Preliminary planning
Pine Tree Wind & Expansion	Wind Turbine	135 MW	n/a	Kern County	Preliminary planning
RE Distributed Solar Project	Solar Photovoltaic	221 MW	1,709	Kern County	Notice of Preparation for a Draft EIR filed Jan. 2011
Ridge Rider Solar Park Project	Solar Photovoltaic	38 MW	475	Kern County	Notice of Preparation of a Draft EIR filed March 2010
Rising Tree Wind Farm	Wind Turbine	234 MW	2,745	Kern County	Notice of Intent to prepare a EIS/EIR filed Jan. 2011
Rosamond Solar Array	Solar Photovoltaic	155 MW	1,177	Kern County	Notice of Preparation of a Draft EIR filed March 2010
Rosamond Solar Project	Solar Photovoltaic	120 MW	960	Kern County	Approved by Kern County Nov. 2010
Sand Canyon Wind Projects	Wind Turbine	40 MW	300	Kern County	Notice of Preparation of a Draft EIR filed Oct. 2010
Willow Springs Solar Array Project	Solar Photovoltaic	160 MW	1,402	Kern County	Notice of Preparation of a Draft EIR filed March 2010
Windstar Wind Energy Project	Wind Turbine	65 MW	1,007	Kern County	Approved by Kern County April 2009

There are also plans in various stages of development to establish additional wind and solar energy projects on BLM land in the Project vicinity. The submission of an application to BLM is a preliminary step in the project planning process, but not all applications ultimately result in successful project development. Below is a list of current applications for wind and solar energy generation projects in the Project vicinity submitted to BLM's Ridgecrest Field Office as of February 2010 (U.S. Department of the Interior, Bureau of Land Management – Renewable Energy).

TABLE 8-2. BLM RIDGECREST OFFICE APPLICATIONS FOR WIND AND SOLAR ENERGY GENERATION PROJECTS IN THE PROJECT VICINITY.

Serial Number	Applicant	Date Application Received, ROW Grant Issued, Last Amended Date	Approximate Area (Acres)	Project Type	Location
CACA 46978	Sean Roberts, Renewable Land LLC	7/1/04	528	Pending Wind	Mojave
CACA 47848	Oak Creek Energy	1/11/06	7,349	Pending Wind	Lucchese
CACA 48536	Oak Creek Energy	7/25/06	1,800	Pending Wind	Soledad Mountain Wind Project
CACA 48820	First Solar (Formally OptiSolar Inc.)	12/13/08	5,760	Pending Solar	Mojave Area

Serial Number	Applicant	Date Application Received, ROW Grant Issued, Last Amended Date	Approximate Area (Acres)	Project Type	Location
CACA 49577	Power Partners SW (enXco)	8/10/07	1,816	Pending Wind	Soledad area
CACA 50171	AES SEAWEST INC	7/3/09	120	Pending Wind	Kern County
CACA 50768	Riverside Wind Energy LLC	4/20/09	480	Pending Wind	Gorman
CACA 51016	Advanced Dev Services, Inc	4/30/09	11,174	Pending Wind	Kern County
CACA 51335	Alta Windpower Dev., LLC	7/13/09	584	Pending Wind	Kern County
CACA 51561	Power Partners Southwest	12/11/09	1,160	Pending Wind	Kern County

Other Major Projects

Transportation and Public Facilities

California High Speed Rail – This project proposes a ±700-mile high speed rail line from Sacramento to San Diego. The Statewide Programmatic EIS/EIR was completed in 2005, and the Bay Area to Central Valley High-Speed Train Program EIS/EIR was completed in 2008. Multiple second-tier project-level environmental documents (with preliminary engineering design) are currently underway (California High Speed Rail Authority).

Pacific Pipeline Storm Relocation Project and Access Road Repairs – Pacific Pipeline is proposing to relocate several miles of crude oil pipeline to more stable ground within the ANF. Project implementation was expected in November 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Antelope Valley Water Bank Project – This project proposes to develop facilities to store and recharge imported surface water and associated delivery and distribution pipelines. The 13,440-acre facility area would be bounded by the Kern/Los Angeles County border line (also known as Avenue A) to the south and Rosamond Boulevard to the north, and between 170th Street West and 100th Street West in unincorporated Kern County (U.S. Department of the Interior, Bureau of Reclamation – Mid-Pacific Region).

Soledad Canyon Cemex Project – The Soledad Canyon Cemex project would be a 56-million-ton sand and gravel mining project in the Soledad Canyon area. The BLM approved the project with mitigating measures in 2000, and the Interior Board of Land Appeals affirmed that decision in 2002. A City of Santa Clarita challenge to the US Supreme Court was denied in 2006. This project is pending development with ongoing challenges and delays (Cemex United States).

Community Development

Centennial, California – The proposed project site consists of 12,000 acres located one mile east of Interstate 5 (I-5) and adjacent to State Highway 138 in Los Angeles County. The project would include a specific plan and subdivision entitlements (i.e., tract maps and conditional use permits) for a master planned community. The specific plan proposes a maximum of 23,000 dwelling units and 14 million total square feet of non-residential development of employment areas (12,233,390 square feet) and retail serving centers (1,986,336 square feet), anticipated to be built over approximately 20 years, with build-out expected in 2030. If the project is approved by Los Angeles County, it is estimated that the non-residential development may generate approximately 31,000 jobs. The draft Specific Plan for the unincorporated community of Centennial was submitted to Los Angeles County in February 2003 and is currently being reviewed by the county (Centennial, California).

Maintenance and Landscape Management Projects

Bouquet Canyon Road Realignment – Los Angeles County Department of Public Works is proposing to straighten some sections of Bouquet Canyon Road and to raise the road surface by approximately nine feet. A Memorandum of Understanding between ANF and Los Angeles County is currently under development to initiate the project (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

San Francisquito Road Rehabilitation and Sediment Disposal Site – Los Angeles County Department of Public Works is proposing a road realignment and new bridge along San Francisquito Road within the ANF and to use eight acres of Forest land as a spoils site in support of construction activities. Public Scoping began in June 2007, and a decision was expected in September 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Old Ridge Route Storm Damage Repair – USFS is proposing to repair and provide maintenance to seven storm-damaged locations along the Old Ridge Route in ANF. A decision on the project is expected in late 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Livestock Grazing Allotments – BLM currently authorizes both cattle and sheep grazing on 11 grazing allotments in and around the project area. The livestock are authorized with 10 year permits/leases and yearly authorizations. These allotments encompass over one half million acres of BLM-managed lands. The number of livestock grazed each year depends upon weather conditions. The majority of the livestock are sheep. The number of sheep average around thirty thousand head. Three of the allotments support several thousand head of cattle (Harris 2010).

Tule Ridge/South Portal Fuels Reduction Project – USFS proposes fuels reduction and re-establishment of a fuel break to provide protection to unincorporated community of Green Valley. The project would also enhance wildlife for mammals and birds (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Jupiter Fuelbreak Project – USFS proposes to re-establish an existing fuel break that begins southwest of the unincorporated community of Green Valley and travels east, bisecting Jupiter Mountain, before heading south to Bouquet Reservoir.

Santa Clara/Mojave River Rangers District Plantation Maintenance Project – The proposed project would consist of vegetation maintenance at 13 plantations located within the ANF in order to reduce wildfire risk, and improve wildlife habitat and the vitality of individual remaining trees. Proposed actions include removal of dead trees, thinning of live trees, pruning, removing weeds, and planting for reforestation where necessary. This action was approved by the District Ranger in January 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Lake Hughes Plantation Restoration Project – The proposed project would restore unauthorized off-highway vehicle trails at the Christian and Taylor Plantations located within the ANF in order to reduce soil erosion, the spread of weeds, destruction of native plants, soil compaction, and wildlife habitat loss. Proposed actions include recontouring and decompacting soils, reseeding with native species, and reinforcing check dams. The project was approved by the District Ranger in 2009 and scheduled for implementation in January 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Bouquet and San Francisquito Habitat Improvement Project – The project proposes invasive species removal in Bouquet and San Francisquito Canyons (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Local Projects

In conjunction with the major projects listed above, a summary of local foreseeable projects within the study area that could contribute to cumulative effects are summarized in the table below. These proposed projects were gathered from applications to the planning departments of the various jurisdictions and have been categorized by project type.

TABLE 8-3. PROPOSED LOCAL PROJECTS IN THE PROJECT VICINITY.

	Kern County	Los Angeles County[1]	City of California City	City of Palmdale[2]	City of Lancaster	City of Santa Clarita	City of Los Angeles	City of San Fernando
Single Family Residential (may include multiple units)	1	96	0	14	93	10	2	2
Multi Family Residential (may include multiple units)	28	9	0	9	2	1	2	1
Schools	2	2	0	9	2	0	0	0
Religious Uses	10	7	0	13	0	0	1	1
Recreational Facilities	7	5	0	7	1	0	0	1

Aviation Facilities	2	0	0	0	0	0	0	0
Non-Commercial Energy Facilities	1	2	0	0	0	0	0	0

[1] Projects listed for Los Angeles County include all projects that could contribute to cumulative effects within the following County Districts: Antelope Valley West, Bouquet Canyon, Castaic Canyon, Chatsworth, Lancaster, Leona Valley, Mount Gleason, Newhall, North Palmdale, Palmdale, Quartz Hill, Sand Canyon, Soledad. Some identified projects included may be outside of the study area.

[2] Projects listed for the City of Palmdale include all projects that could contribute to cumulative effects within the City. Some identified projects included may be outside of the study area.

8.4.4. Direct and Indirect Impacts Summary

Construction and operation of the BRRTP alternatives would potentially impact water quality through ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction.

Disturbed soils accelerate erosion and increase sediment in stormwater runoff to receiving waters, causing increased turbidity and sedimentation. Additionally, fuel, oil, and other fluids used in construction vehicles, equipment, and heavy machinery could enter streams and contaminate water. Project-related ground disturbance could potentially alter drainage patterns within the work areas and result in soil erosion leading to increased sedimentation or increase of the rate or amount of surface water runoff. Grading activities could also potentially create additional sources of runoff, including polluted runoff.

Dewatering during construction activities could potentially release contaminated groundwater to surface water channels or drainage features. Construction of the project could also result in adversely impacting wetlands by removing or degrading wetland soils, damaging or removing wetland plants, or disrupting wetland hydrology. The project would also result in placement of structures within a 100-year floodplain.

Many of the present and reasonably foreseeable projects described above involve grading activities, including large-scale grading activities that would continue for years after the BRRTP is completed. These projects would have potential to affect the impact area by altering drainage patterns, accelerating erosion, and adding additional sediment to local drainages.

Compacted or new paved areas, including railroad beds, would potentially increase the rate or amount of stormwater runoff, or create additional sources of stormwater runoff. Polluted runoff could be introduced to the impact area as oil products collect on new paved surfaces and are washed into the system with stormwater runoff. Projects using improper dewatering procedures could release contaminated groundwater into drainages within the impact area.

Along the foothills and drainages of the Tehachapi Mountains and the San Andreas Rift Zone are PEM and PFO wetlands that could be filled by at least one project, and could be impacted by altered soils, vegetation, or hydrology resulting from other projects.

Most of the projects described above cross or are located within FEMA 100-year floodplains, and would place structures within a 100-year floodplain, potentially impeding or redirecting flood flows.

8.4.5. Cumulative Effects Evaluation

Whenever multiple activities at a single site, or activities at multiple sites, produce similar or complimentary changes to environmental parameters or watershed processes, the resulting impacts can be cumulatively significant, even if they are individually insignificant. For example, soil compaction resulting from construction vehicles driving over a natural surface decreases pore space and collapses conduits between pores, reducing soil porosity and permeability, and increasing runoff rates, which causes erosion. Likewise, replacement of natural surfaces with impermeable material allows a high stormwater runoff ratio and increases both peak flows and total flow volume. Removal of topsoil which leaves mineral soil exposed also increases the rate of stormwater flow, which in turn creates more erosion (Reid 1993). Increased and eroding stormwater flows carry increased sediment load into drainages, which increases turbidity. When these processes are occurring at multiple sites, sediment load can increase turbidity such that water temperature can increase, which in turn decreases the level of dissolved oxygen, which can lead to increased stress or death of aquatic animals.

Polluted stormwater runoff could introduce petroleum products or pathogens, or otherwise alter water chemistry, including pH levels. Runoff from multiple sources could lead to water quality impacts that exceed water quality objective thresholds. In addition, some introduced chemicals can alter the mobility or chemical composition of chemicals already present, and may contribute to nutrient deficiencies or inhibit the ability of plants to make use of available nutrients. Introduced chemicals may be deposited within streams, and repeated addition of chemicals may cause a cumulative increase in concentration (Reid 1993).

When topography is altered for construction purposes, the change in natural contours can change local and downstream hydrology. Altered hydrology can decrease water availability to wetlands, which would impact in wetland plant populations and eventually create upland conditions. Altered hydrology can also modify the timing and amount of storm runoff, which could change base flows, peak flows, and flood seasonality. In response to these changes flood frequencies could change, stream channels could aggraded, incised, or widened, and the size distribution of streambed sediment would be modified (Reid 1993). These effects would not be limited to the physical environment, but would also affect wetland and riparian plant populations and aquatic animal populations. Changes in flood frequency and distribution could also affect human populations.

Impacts that are individually less than significant are cumulatively significant if they contribute incrementally to a cumulative impact that is already significant. For example, if a project results in sedimentation impacts that are less than significant on a project-level basis, the cumulative impact from sedimentation can be significant if the sediment is released into a stream that has not yet recovered from previous sedimentation impacts. Potential impacts to water resources resulting from construction and operation of the BRRTP may be less than significant; however, even with implementation of mitigation measures and GPs, they will have a cumulative effect on the watersheds in which they occur as they add to the impacts of past and contemporary projects, and as the impacts of future projects are added to them. While project-level mitigation measures and GPs are not sufficient to negate cumulative watershed effects, effectively implemented they are an important component of a broader watershed-scale approach to recovery from human activities.

1.0 INTRODUCTION

The City of Los Angeles Department of Water and Power (LADWP) is proposing the Barren Ridge Renewable Transmission Project (BRRTP or Project) to access clean, renewable resources in the Tehachapi Mountain and Mojave Desert areas. The Project is approximately 76 miles in length, beginning at the Barren Ridge Switching Station to Rinaldi Substation, and extends approximately 12 miles from the Castaic Power Plant to the proposed Haskell Switching Station. The proposed BRRTP includes the following:

1) Construction of approximately 61 miles of a 230 kilovolt (kV) double-circuit transmission line from the LADWP Barren Ridge Switching Station to Haskell Canyon;
2) Addition of approximately 12 miles of a 230 kV circuit on the existing double-circuit structures from Haskell Canyon to the Castaic Power Plant;
3) Upgrade of approximately 76 miles of the existing Barren Ridge-Rinaldi (BR-RIN) 230 kV transmission line with larger capacity conductors between the Barren Ridge Switching Station and the Rinaldi Substation;
4) Construction of a new electrical switching station in Haskell Canyon;
5) Expansion of the existing Barren Ridge Switching Station.

Portions of each of the three Project alternative routes would cross through the Angeles National Forest. Temporary impacts would occur where ground is disturbed for equipment staging and line work, and where construction access would be needed. Permanent impacts would result from ground disturbance required for upgrading the existing access roads and spur roads, and clearing the right-of-way.

Initial analysis of Project-related impacts revealed the potential for impacts to water quality through erosion of disturbed soils, leading to increased sedimentation and turbidity of receiving waters within the Angeles National Forest. At the request of the U.S. Forest Service (USFS), POWER Engineers, Inc. has prepared a watershed analysis to predict erosion rates (tons/acre/year) that would potentially result from construction of the alternative transmission line routes in the Angeles National Forest. This analysis allows for the comparison of potential impacts on sensitive aquatic habitat and species, and beneficial uses of waters from construction of the alternative routes within the Angeles National Forest.

2.0 METHODOLOGY

Following consultation with Mr. Paul Gregory, Hydrologist for the Angeles National Forest, the Revised Universal Soil Loss Equation, Version 2 (RUSLE) was selected to predict annual erosion from Project-related ground disturbance. The RUSLE model was run using ESRI ArcGIS 9.3.1 software. The RUSLE model predicts long-term average annual soil loss expressed in tons per acre per year (A), and is determined by the product of five factors:

$$A = R \cdot K \cdot LS \cdot C \cdot P$$

where:

A = Estimated soil loss in tons per acre per year
R = Rainfall-erosivity factor
K = Soil erodibility factor
LS = Slope length and slope steepness factor
C = Land cover management factor
P = Erosion control practice factor

The R factor represents the erosivity due to rainfall at a particular location. An average annual value of R is determined from historical weather records using erosivity values determined from individual storms, computed as the average annual sum of EI_{30}, where E is total storm kinetic energy and I_{30} is the maximum 30-minute storm intensity. The R factor accounts for both the intensity and amount of rainfall. This analysis used 4-kilometer resolution data acquired from the Natural Resource Conservation Service (NRCS) National Water and Climate Center in Portland, Oregon. This data was then converted to a 10-meter grid for calculation purposes.

The K factor represents the susceptibility of a soil to sheet and rill erosion by water. The estimates are based primarily on percentage of silt, sand, and organic matter, and on soil structure and saturated hydraulic conductivity (Ksat). For example, silt soils generally have the highest K values because silt soil particles detach easily and the sediment is easily transported. Soils with high clay content have the lowest K values because clay soils are generally plastic and resistant to detachment. K factor values from Kern, Los Angeles, and Ventura county soils were assigned based on dominant component Soil Survey Geographic (SSURGO) data from the NRCS database. Within the study area, values of K range from 0.02 to 0.32. This data was then converted to a 10-meter grid for calculation purposes.

The LS factors represent the effects of topography on erosion. The L factor represents hillslope length and the S factor represents hillslope gradient. In general, soil loss increases with increased hillslope length and gradient. To calculate the LS factor, 10-meter digital elevation model data was obtained from USGS. An automated program, RUSLE_LS_4_PC (Van Remortel *et. al.* 2007) was used to account for changes in slope from cell to cell by using a slope cut-off factor for ending/beginning slope length cumulation. For this analysis, the default cutoff values were used; a cutoff factor of 0.7 feet was used for slopes of less than five percent, and a cutoff factor of 0.5 feet was used for slopes greater than or equal to five percent.

The C factor represents the effects of land cover; specifically, the effects of vegetative cover, soil cover, soil biomass (roots and incorporated residue), and soil-disturbing activities on erosion. The C value is the average soil loss ratio weighted by the distribution of rainfall (EI) during the year. This study used a National Land Cover Dataset (NLCD) adjusted with wildfire perimeter data. The NLCD data was adjusted for both the base level RUSLE model and the proposed Project RUSLE model, to account for fires within the last 10 years. Fire data was incorporated based on the year of the burn and changing cover classes within burn areas based on the number of years since the burn occurred (see Table 1).

TABLE 1. NLCD CODES AND VEGETATION CLASSES ADJUSTED BY BURN YEAR

Burn Year	Adjusted NLCD Code and Vegetation Cover Class
2009	31 – Barren Land (Rock/Sand/Clay)
2008	31 – Barren Land (Rock/Sand/Clay)
2007	71 – Grassland/Herbaceous
2006	71 – Grassland/Herbaceous
2005	71 – Grassland/Herbaceous
2004	71 – Grassland/Herbaceous
2003	71 – Grassland/Herbaceous
2002	52 – Scrub/Shrub
2001	52 – Scrub/Shrub
2000	52 – Scrub/Shrub
1999	52 – Scrub/Shrub

Areas where fires occurred recently (2008 and 2009) were given a vegetation cover class of “barren land” since the fires had consumed all vegetation covers and soils were exposed. Over time, these areas begin to recover, with establishment of grasses and herbaceous vegetation, followed by scrub/shrub or woody vegetation providing increased soil cover and stability.

Data for areas within the Angeles National Forest indicates that annual erosion rates during the first year after a burn are 30 times greater than baseline levels. The second year after a burn, erosion rates decrease to 10 times baseline followed by seven times greater the third year, five times greater the fourth year, four times greater the fifth year, three times greater the sixth year, and two times greater the seventh year. By eight to ten years following the burn, the area has typically recovered to baseline levels (Rowe *et. al.* 1949).

For analysis of erosion resulting from the Project, C values were adjusted based on Project-related changes (*e.g.*, road construction or improvement of existing roads). The NLCD was modified for each proposed alternative where roads would require improvement. Roads requiring improvement were buffered by five meters, and underlying values (one 10-meter grid cell) were designated "barren land." Based on RUSLE2 software, RUSLE calculation procedure manuals, correlation tables, and approximate ranges from previous analyses, NLCD codes were correlated and converted to C values, as shown in Table 2. The adjusted C values were then converted to a 10-meter grid.

TABLE 2. C-FACTOR VALUES

C Factor	NLCD Code Number	Description
0	11	Open Water
0.01	21	Developed Open Space
0.01	22	Developed, Low Intensity
0.02	23	Developed, Medium Intensity
0.03	24	Developed, High Intensity
0.3	31	Barren Land
0.003	41	Deciduous Forest
0.003	42	Evergreen Forest
0.003	43	Mixed Forest
0.06	52	Scrub/Shrub
0.05	71	Grassland/Herbaceous
0.02	81	Pasture/Hay
0.09	82	Cultivated Crops
0.0003	90	Woody Wetlands
0.0006	95	Emergent Herbaceous Wetlands

The P factor represents the influence of control practices, such as contour farming, terracing, diversions, or sediment- and erosion-control best management practices (BMPs) that reduce the erosion potential of stormwater runoff. Although the P factor can be modified to account for construction disturbance and associated effectiveness of mitigation features, this variable was held constant throughout this analysis. Assignment of P values for specific disturbance and BMPs is impractical for an analysis of this scale. For an analysis of this scale, using a constant value of P is considered a conservative approach if the total area modified with increased land use factors (C factor) due to construction is overestimated. This is the case with this analysis, since C factor values were assigned in 10-meter grid increments.

Given the scale of the study area, specific data regarding implementation of erosion- and sediment-control BMPs were not included in this analysis ($P = 1$), and predicted post-construction erosion values do not reflect effects of BMP implementation. In actuality, erosion- and sediment-control BMPs and mitigation measures would be implemented throughout the Project and would reduce the potential for erosion and sedimentation.

The boundary of the watershed study area was delineated using twelve-digit/6th level hydrologic units encompassing the alternative routes within the Angeles National Forest. All data was clipped to this study area before running the RUSLE analyses.

3.0 RESULTS AND DISCUSSION

The study area encompasses 333,135 acres of highly varied terrain within the Angeles National Forest. The study area was divided according to watersheds affected by routing alternatives of the Project. The watersheds evaluated in this assessment are 6th level subwatersheds (12-digit hydrologic unit codes [HUCs]) ranging from approximately 11,409 acres to 38,533 acres and elevations of approximately 960 feet to 3,550 feet. Using the RUSLE model, baseline annual erosion rates (tons/acre/year) were estimated for each subwatershed affected by the alternative routes (Alternatives 1, 2, and 3) as shown in Figure 1. Four subwatersheds within the study area would not be affected by the BRRTP alternatives: Elizabeth Lake Canyon (180701020304), Fish Creek-Piru Creek (180701020602), Fish Canyon (180701020302), and Upper Bouquet Canyon (180701020201).

Once baseline values were estimated, the change in annual erosion rates (tons/acre/year) was estimated for each subwatershed as a result of construction of the alternative routes (*e.g.*, vegetation clearing related to road construction). Using these results, the increase of erosion from baseline conditions was calculated.

Alternative 1 would affect eight subwatersheds with a combined area of 191,957 acres. Sensitive aquatic species within these subwatersheds are arroyo toad (*Anaxyrus californicus*), California red-legged frog (*Rana draytonii*), and the Santa Ana sucker (*Catostomus santaanae*). As detailed in Table 3, estimated average baseline annual erosion level for these subwatersheds is 48.15 tons/acre/year. With construction of Alternative 1, predicted average erosion levels would be 48.43 tons/acre/year, and increase of 0.68 percent over baseline conditions. Of the eight subwatersheds, Liebre Gulch-Piru Creek would have the largest potential increase (2.26 percent) over baseline conditions from construction of Alternative 1.

Alternative 2 would affect three subwatersheds with a combined area of 65,172 acres. Sensitive aquatic species within these subwatersheds are the arroyo toad and the California red-legged frog. As detailed in Table 4, estimated average baseline annual erosion level for these subwatersheds is 43.93 tons/acre/year. With construction of Alternative 2, predicted average annual erosion would be approximately 44.43 tons/acre/year, an increase of 1.18 percent over baseline. Of the three subwatersheds, Elizabeth Lake would have the largest potential increase (1.59 percent) over baseline conditions from construction of Alternative 2.

Alternative 3 would affect three subwatersheds with a combined area of 76,006 acres. Sensitive aquatic species within these subwatersheds are the arroyo toad, California red-legged frog, and the Santa Ana sucker. Estimated average baseline annual erosion level for these subwatersheds is 35.42 tons/acre/year. As detailed in Table 5, with construction of Alternative 3, predicted average annual erosion would be 35.82 tons/acre/year, an increase of 1.35 percent over baseline. Of the three subwatersheds, Agua Dulce Canyon would have the largest potential increase (2.04 percent) over baseline conditions from construction of Alternative 3.

Rates of erosion are dependent on scale. Smaller watersheds at higher elevations tend to have higher predicted rates of erosion than larger watersheds at lower elevations. In the Angeles National Forest, smaller watersheds generally have steeper slopes and greater relief, tend to receive a greater amount of precipitation than lower-lying watersheds, and are flushed more readily by storm runoff. Vegetation also plays a role in erosion, acting as a biological barrier by intercepting precipitation and causing it to dissipate its kinetic energy on leaves and other plant structures (Howard 1982). When vegetation is removed, either by natural means (*e.g.*, wildfires) or by artificial means (*e.g.*, vegetative clearing for construction purposes), soils are left relatively open to erosive influences.

Traditionally, the RUSLE model has been applied to agricultural lands where the cover is relatively uniform and slopes are relatively level. Since its development, use of the RUSLE model has been extended to predict erosion in such non-traditional settings as construction sites, reclaimed mine spoils, and erosion on steep slopes in the tropics. In non-traditional settings where the RUSLE model generates a value for A of > 20 tons/acre/year, the expected accuracy rate is ± 35 percent (Yoder *et. al*. 2001).

The purpose of this analysis was not to calculate a precise quantity of sediment delivered to catchments within the study area, but to use the predicted volumes of soil loss to qualitatively compare the erosional effects of each BRRTP alternative route within the Angeles National Forest. In this respect, the predicted magnitude of change between pre- and post-project erosion, and between each alternative, is more useful to planners than a precise prediction of sediment delivered to a given outlet. The results of this analysis will allow for a side-by-side comparison of potential impacts from erosion resulting from each alternative, and allow for a more specific assessment of Project-related potential impacts to sensitive aquatic species within the study areas.

A RUSLE analysis was conducted for the Tehachapi Renewable Transmission Project (TRTP), also located partially within the Angeles National Forest (SCE 2009). Fourteen catchments were modeled in the TRTP analysis; catchment areas ranged from 1,879 acres to 55,471 acres (average area 19,989 acres), and predicted post-project annual erosion levels ranged between 3.6 tons/acre/year and 31.5 tons/acre/year. Predicted annual erosion increase over base values ranged from 0.4 percent to 13.0 percent (average increase over base was 4.06 percent). Predicted erosion increases predicted for the BRRTP are consistent with values predicted for the TRTP, especially considering similarities in terrain, rainfall levels, fire history, and vegetation cover between the two study areas.

It is important to note that the predicted rates of erosion do not reflect the amount of sediment that would be transported out of the watersheds; rather, the predicted values are an estimation of erosion that would occur as a result of construction and operation of the BRRTP. In actuality, much of the sediment eroded from construction areas and roads would be redeposited before leaving the watershed. A Spatially Explicit Sediment Delivery Model (SEDMOD) would be required to predict the quantity of eroded material that leaves the watersheds as sediment.

SEDMOD is expressed as follows:

$$SDR = 39\ A^{-1/8} + \Delta DP$$

Where SDR = sediment delivery ratio
A = watershed area in square kilometers
ΔDP = difference between the composite delivery and its mean value

Delivery Potential is determined as follows:

$$DP = (SG)r(SG)w + (SS)r(SS)w + (SP)r(SP)w + (ST)r(ST)w + (OF)r(OF)w$$

Where SG = slope gradient
SS = slope shape

SR = surface roughness
SP = stream proximity
ST = soil texture
OF = overland flow index
r = parameter rating (1 – 100)
w = weighting factor (0 – 1)

Once gross soil loss and sediment delivery ratio are determined, sediment load is estimated as follows:

$$SY = A \cdot SDR$$

Where SY = Sediment Yield
A = Gross Soil Loss
SDR = Sediment Delivery Ratio

SEDMOD modeling was outside the scope of this analysis; however, SEDMOD modeling using RUSLE analysis results for the TRTP watersheds estimated that only 10 percent of the predicted annual erosion would reach the catchment outlets as sediment (SCE 2009). Taking into account the similarities of topography, soils, and watershed areas between the TRTP and the BRRTP study areas, it is reasonable to expect similar predicted sediment delivery values for the BRRTP study area.

It is also important to note that, due to the scale of this analysis, the predicted post-Project erosion values do not reflect implementation of BMPs or mitigation measures. Where site conditions are modeled assuming implementation of BMPs, RUSLE erosion predictions are from 52 percent to 93 percent lower than without BMP implementation (Wachal *et. al*. 2008).

The post-Project erosion rates predicted in this analysis represent a worst-case scenario in which no BMPs or mitigation measures are implemented and all eroded material leaves the study area as sediment. The BRRTP would implement appropriate erosion- and sediment-control BMPs and mitigation measures throughout all stages of construction. Furthermore, the model reflects erosion rates within the first year after construction, and does not account for natural revegetation. Assuming the more conservative estimate of 52 percent reduction in erosion rates, implementation of erosion- and sediment-control BMPs and mitigation measures would reduce average predicted post-Project erosion rates in Alternative 1 to 48.30 tons/acre/year, in Alternative 2 to 44.18 tons/acre /year and in Alternative 3 to 35.63 tons/acre/year. Increases in erosion rates over base would average 0.33 percent in Alternative 1, in Alternative 2 to 0.58 percent, and in Alternative 3 to 0.64 percent.

APPENDIX C: DETAILED CONSTRUCTION, OPERATION AND MAINTENANCE PROCESS

THIS PAGE INTENTIONALLY LEFT BLANK

BARREN RIDGE RENEWABLE TRANSMISSION PROJECT

Detailed Construction, Operations and Maintenance Process

POWER ENGINEERS

BRRTP CONSTRUCTION, OPERATION AND MAINTENANCE

1.0 230 KV DOUBLE-CIRCUIT TRANSMISSION LINE

1.1 CONSTRUCTION SEQUENCE

Construction of a transmission line involves the following general sequence of events: surveying the centerline; identifying and constructing access roads; clearing right-of-way and tower sites (including construction yards and batch plants); installing foundations; assembling and erecting the towers; clearing, pulling, tensioning, and splicing sites; installing ground wires and conductors; installing counterpoise; switching station tie in; and cleanup and site reclamation. Various phases of construction would occur at different locations throughout the construction process for the Barren Ridge Renewable Transmission Project (BRRTP). This would require several contractors operating at the same time and in different locations.

The following section describes the construction components necessary for the assembly and installation of the proposed double-circuit transmission line. The description of transmission line construction sequencing and estimates for construction sites would also be relevant for the additional transmission line construction activities associated with the installation of the Castaic-Haskell Canyon #4 circuit on existing structures, and the reconductoring of the Barren Ridge – Rinaldi (BR-RIN) transmission line between the Barren Ridge Switching Station and the Rinaldi Substation.

1.1.1 Surveying Activities

The Los Angeles Department of Water and Power (LADWP) must first obtain survey permits for the portion of the Project crossing federal lands managed by the U.S. Department of Agriculture, Forest Service (USFS) and the U.S. Department of the Interior, Bureau of Land Management (BLM), and rights-of-entry for private lands. This would include the issuance of a 50-year term Special Use Permit to LADWP by the USFS and a 30-year term (renewable) Right-of-Way Grant issued by the BLM. For survey on affected private lands, LADWP would need to negotiate rights-of-entry with the local landowners. Once survey permits are obtained, construction survey work would consist of locating the centerline, tower center hubs, ROW boundaries, and tower access roads, some of which would be located outside of the ROW boundaries. Whenever possible, location of the ROW and Project facilities would be laid out to avoid identified sensitive resources. All of these activities would begin approximately one year prior to the start of construction. Cultural resources and necessary additional threatened and endangered species intensive surveys would be conducted once the survey of the centerline and access roads is completed and clearly marked.

Necessary pre-construction geotechnical investigations would include geological field mapping of each tower site, and borings by drill rig for soil sampling and bedrock corings to determine soil densities and bedrock strength. Test locations would include angle points between the Barren Ridge Switching Station and the Angeles National Forest (ANF), and five to ten locations along the selected alignment within the ANF. Seismic analysis of tower sites for slope stability would also be necessary in mountainous areas of the ANF. Existing roads would be used as much as possible, but some new roads could be required.

1.1.2 Preconstruction Weed Removal

LADWP/ANF/BLM shall prepare and implement a comprehensive, adaptive Weed Control Plan on NFS/BLM lands for pre-construction and construction invasive weed abatement. A pre-construction weed inventory shall be conducted by surveying all areas subject to ground-disturbing activity, including, but not limited to, tower pad preparation and construction areas, tower removal sites, pulling and tensioning

sites, assembly yards, and areas subject to grading for new or improved access and spur roads. In areas subject to ground disturbance, weed infestations shall be treated prior to construction according to control methods and practices for invasive weed populations designed in consultation with the USFS/BLM. The Weed Control Plan shall be updated and utilized for eradication and monitoring post construction. Weed control treatments shall include all legally permitted herbicide, manual, and mechanical methods applied with the authorization of the USFS/BLM. The application of herbicides shall be in compliance with all state and federal laws and regulations under the prescription of a Pest Control Advisor (PCA), where concurrence has been provided by the USFS/BLM, and implemented by a Licensed Qualified Applicator. Herbicides shall not be applied during or within 24 hours of a scheduled rain event. Herbicides shall not be used within Riparian Conservation Areas (RCAs) on the ANF without approval of the USFS. In riparian areas, only water-safe herbicides shall be used. Herbicides shall not be applied when wind velocities exceed six miles per hour. Where manual and/or mechanical methods are used, disposal of the plant debris will follow the regulations set by the USFS/BLM. The timing of the weed control treatment shall be determined for each plant species in consultation with the USFS/BLM (on NFS/BLM lands, respectively) with the goal of controlling populations before they start producing seeds.

1.1.3 Construction of Access Roads

The construction, operation, and maintenance of the proposed transmission line would require that heavy vehicles access tower sites along the right-of-way. Where new access roads are required, they would be constructed to support the weight of these vehicles and would typically be 16 feet wide, consisting of a 14-foot driving surface with a side drainage system between one and two feet in width. Permanent roads would be constructed where necessary for operation or maintenance, or where it is required by the landowner or land managing agency. Road standards would be addressed specifically in the Construction, Operation, and Maintenance Plan (COM Plan) and the Plan of Development (POD) during the engineering phase of the Project, and prior to a Notice to Proceed from the USFS and BLM.

Dependent upon final design and mitigation, some temporary access roads may be constructed as part of the Project. These would typically be 16 foot wide roads, but would typically have no improved ditch drainage systems. Most temporary roads would be constructed by crushing vegetation. In some areas, material and topsoil from the temporary roads would be bladed to one or both sides to facilitate rehabilitation. Following construction, bladed material can be re-spread across the disturbed road section. Seeds and roots contained within the re-spread topsoil layer normally provide a natural source for new growth.

Existing paved and unpaved highways and roads would be used where possible. Roads along existing utility corridors would also be used where possible to minimize new access road construction. In locations where existing roads can be used that are located in close proximity to the proposed centerline of the transmission line, only spur roads to the tower sites would be required. New access roads and spur roads would likely be constructed into the right-of-way where existing roads do not exist. Table 1 lists the estimated ground disturbance of access and spur roads based on terrain.

TABLE 1. ACCESS AND SPUR ROAD GROUND DISTURBANCE ESTIMATES

Ground Disturbance Categories	Access Roads		Spur Roads (average width 16 feet)	
	Average Miles of Roads Per Mile of Transmission Line	Average Acres of Disturbance Per Mile of Transmission Line*	Average Miles of Roads Per Mile of Transmission Line	Average Acres of Disturbance Per Mile of Transmission Line
1. Existing roads or agricultural land; no widening anticipated	n/a	n/a	0.3	0.6
2. Existing 8 ft wide roads that require an additional 8 ft of widening	1.0 to 2.5	Permanent 0.9 to 2.4	0.3	0.6
3. Construct new road on flat terrain (0-10%)	1.0 to 2.5	Permanent 1.9 to 4.8	0.3	0.6
4. Construct new road on sloping terrain (10-20%)[1]	2.5 to 4.0	Temporary 7.3 to 11.6 Permanent 4.8 to 7.7	0.5	1.0
5. Construct new road on steep terrain (20-30%)[1, 2]	4.0 to 6.0	Temporary 23.3 to 34.9 Permanent 7.7 to 11.6	0.8	1.6
6. Construct road on very steep terrain (greater than 30%)[1, 2]	6.0 to 8.0	Temporary 69.8 to 93.1 Permanent 11.6 to 15.5	1.0	1.9

[1] After construction of the transmission line, all access roads in Categories 4 through 6 would be restored back to 16 feet wide.

[2] On steep terrain (approximately 25% or higher) with limited access on the Angeles National Forest, the USFS may require Helicopter Mitigation.

Wherever possible, roads would be built at right angles to streams and washes. Culverts or other drainage structures would be installed as necessary across drainages, but the roads would usually follow the natural grade. In addition, road construction would include dust-control and erosion control measures in sensitive areas. All existing roads would be left in a condition equal to or better than their condition prior to the construction of the transmission line without changing their service level. Gates would be installed where required at fenced property lines to restrict general vehicular access from or to the right-of-way. Where identified within the environmental studies for mitigation purposes, access roads may be excluded or limited within specific sensitive areas, such as Riparian Conservation Areas (RCAs) on the Angeles National Forest.

1.1.4 Clearing Right-of-Way

The clearing of some natural vegetation may be required. However, selective clearing would be performed only when necessary to provide for surveying, electrical safety clearances, line reliability, and maintenance. Trimming or removal of mature vegetation, under or near the conductors, would be done to provide adequate electrical clearance as required by the National Electrical Safety Code, the North American Electrical Reliability Corporation, and California Public Utilities Commission General Order 95 standards.

Trees that could fall onto the lines or affect lines during wind-induced line swing would be removed. Normal clearing procedures are to top or remove large trees and not disturb smaller trees. Where there is a direct conflict between trees and clearance standards, the removal of trees would be jointly reviewed and agreed upon between LADWP and the owners or managers of the property. Rights-of-way would not be chemically treated unless necessary to comply with requirements of a permitting agency. On National Forest System (NFS) lands, approved herbicides would be utilized within the Project area on select invasive plant species. Invasive plant surveys and control would continue for the life of the Project.

1.1.5 Tower Site Clearing

After access roads are developed, preparation of individual structure sites would be required to install the structures. At tower locations, work areas of up to 200 feet squared in flat terrain and up to 200 by 250 feet in areas with slopes greater than eight percent may be needed. Within the work areas, at some tower locations, a level cleared area (pad) may be necessary to complete the construction of the towers. However, many tower sites would be considerably smaller depending on the size of the tower, the terrain, resource considerations, and whether helicopter construction was used, among other factors. The work area would be required for the location of tower footings, assembly of the tower, and the necessary crane maneuvers. Vegetation would be mostly crushed, and cleared only when necessary. All pads not needed for normal transmission line maintenance would be graded to blend as near as possible with the natural contours, and revegetated where required by a permitting agency. See Table 2 for tower specifications and Table 5 for estimated temporary and permanent ground disturbance associated with the double-circuit steel lattice towers.

TABLE 2. DOUBLE-CIRCUIT STEEL LATTICE TOWER SPECIFICATIONS

Tower Placement Details	Specifications	
	Categories 1 through 3 Flat (0 – 10% slope)	Categories 4 through 6 Mountainous (10 – 30% slope)
Towers per mile	±5	±5
Average span length	1,100 ft.	1,000 ft.
Average height		
Ground to lowest attachment	115 ft.	105 ft.
Upper body height	52 ft.	52 ft.
Overall tower height	167 ft.	157 ft.
Typical range of heights of new towers	120 – 195 ft.	110 – 185 ft.

1.1.6 Staging Areas and Batch Plants

It is anticipated that one or two construction yards or staging areas would be required for materials storage, construction equipment, construction vehicles, and temporary construction offices. Staging areas would be approximately five acres in size, and located centrally or near each end of the transmission line route. The staging areas would be located on previously disturbed private land and would be level and surfaced with crushed aggregate base. The LADWP would negotiate with landowners for specific locations of the staging areas.

Concrete for use in constructing foundations would be dispensed from a portable concrete batch plant located at approximately 15 mile intervals. A rubber-tired flatbed truck and tractor would be used to relocate each plant along the right-of-way. Commercial ready-mix concrete would be used when access to tower construction sites is economically feasible.

The construction yards and batch plants would be located on private land and serve as field offices, reporting locations for workers, parking space for vehicles and equipment, sites for material storage, and stations for equipment maintenance. Facilities would be fenced and their gates locked. Security guards would be stationed where needed. See Table 3 for estimated ground disturbance associated with the staging sites and batch plants.

TABLE 3. STAGING SITES AND BATCH PLANT GROUND DISTURBANCE ESTIMATES

Disturbance Description	**Categories 1 through 3 Flat (0 – 10% slope)***	
	Maximum Estimated Disturbance Dimension per site	**Average Disturbance**
Material staging sites (2 sites)	400 x 540 ft. (5 acres)	N/A
Concrete batch plants (3 sites maximum)	2 acres, 30 mile haul distance	0.2 acre per mile
Total Average Disturbance	**0.2 acre per mile**	

*Material staging sites and concrete batch plants would not be built on terrain above 10% slope.

1.1.7 Foundation Installation

Tower foundations for the lattice structures would consist of drilled concrete piers. The foundation process would start with the boring of four holes for each lattice structure or one hole for each TSP. The holes would be bored using truck- or track-mounted excavators with various diameter augers to match diameter and depth requirements of the foundation sizes.

For a typical suspension lattice tower, each hole would typically be four feet in diameter and 25 feet deep, depending on soil conditions. For the larger angle or dead-end structures, foundations could be up to 30 or more feet deep, depending on soil conditions. Each foundation would extend above the ground line between six inches and four feet. In extremely sandy areas, soil stabilization by water or a gelling agent may be used prior to excavation. Refer to Figure 1 and Figure 2 for typical foundation details for double-circuit towers.

Following excavation of the foundation holes, each footing would be constructed by placing formwork, reinforcing steel and a tower stub into the foundation hole, positioning the stub, and encasing it in concrete. Reinforcing steel cages would be assembled at laydown yards and delivered to each structure location by flatbed truck. Spoil material would be spread around the tower site and used for fill where suitable. The foundation excavation and installation would require access to the site by a power auger or drill, a crane, material trucks, and ready-mix trucks. Typical suspension structures would require approximately 25 to 40 cubic yards of concrete and dead-end structures would require approximately 120 cubic yards of concrete.

1.1.8 Tower Assembly and Installation

The size of the work areas for structures (assembly and installation sites) would be approximately 40,000 to 50,000 square feet (1 acre = 43,560 ft^2) depending on terrain. The location of these sites has not yet been determined, but exact locations would be identified within the COM Plan and POD prior to a Notice to Proceed from the agencies. Lattice towers would be assembled at each site, installed and bolted to the foundations. Bundles of steel members and associated parts would be transported to each tower site by truck. Steel members would be assembled into subsections of convenient size and weight on the ground. Assembly would be facilitated with a small rough-terrain crane. The assembled subsections would be erected into place by a large crane and then fastened together in the air to form a complete tower. See Figure 3 for an illustration of typical tower assembly and installation activities.

FIGURE 3. **TYPICAL TOWER ASSEMBLY AND INSTALLATION ACTIVITIES**

1.1.9 Conductor Installation

After the towers are erected, insulators, hardware, and stringing sheaves would be delivered to each tower site. The towers would be rigged with insulator strings and stringing sheaves at each ground wire and conductor position. Sheaves are rollers, temporarily attached to the lower end of the insulators that allow the conductor to be pulled, or "strung," along the line.

For public protection during wire installation, temporary guard structures would be built next to highways, railroads, power lines, structures, and other major obstacles. Guard structures would consist of

H-frame poles placed on either side of an obstacle. These structures would prevent ground wire, conductor, or equipment from falling on an obstacle. Equipment for installing guard structures would include augers, line trucks, pole trailers, and cranes. A guard structure would be anticipated to be necessary every five miles. The amount of ground disturbance would typically be 200 feet by 300 feet. The guard structures would be left in place until conductors and ground wires were strung, tensioned and clipped; this time frame would be approximately three weeks or longer depending on conditions. Guard structures may not be necessary for small roads. In such cases, other safety measures, such as barriers, flagmen, or other traffic control, would be used.

Pilot lines would be pulled (strung) from tower to tower by a helicopter and threaded through the stringing sheaves at each tower. The pilot line can be used to pull in the ground wire, but is used to pull in a larger-diameter, stronger pulling line for the conductor. The larger-diameter, stronger line—pulling line—would be attached to the conductors to pull them onto towers. This process would be repeated until the ground wire or conductor is pulled through all sheaves. Bundled conductors would be pulled together with the assistance of a running board. The running board attaches the bundled conductor to the pulling line.

Ground wire and conductors would be strung using powered pulling equipment at one end and powered braking or tensioning equipment at the other end of a conductor segment as shown on Figure 4. Sites for tensioning equipment and pulling equipment would be approximately 2.5 miles apart.

REELS OF CONDUCTOR
CLEAN-UP & REHABILITATION
DISCLAIMER: FIGURE NOT TO SCALE

To the greatest extent practical, pulling and tensioning sites would be located within the transmission ROW. However, some pulling and tensioning sites may occur outside the ROW. The tensioning and pulling sites could be as large as 200 feet by 500 feet, however they would be limited in size depending on each specific location and what is reasonable for safe construction practices. The size of each site would be limited as much as possible and would be designed in coordination with the responsible property owner or land management agency. Depending on topography, some grading may be required at pulling and tensioning sites to create level pads for equipment. Tensioners, line trucks, wire trailers, and tractors needed for stringing and anchoring the ground wire or conductor would be located at the tensioning sites. A puller, line trucks, sag cat and tractors would be needed for pulling and temporarily anchoring the ground wire and conductor. Table 5 includes ground disturbance estimates for conductor installation (helicopter fly yards, portable helicopter landing pads, pulling and stringing sites, and sleeving and stringing operations).

After installing the conductor ground wire or fiber optic shield wire, sagging, clipping and dead-ending activities, terminating the conductors at dead-end structures, would be performed. This process would involve adjusting the position of the conductors and shield wires, removing stringing sheaves, and permanently attaching the conductor to the insulators with specialized hardware.

1.1.10 Counterpoise Installation and Grounding Practices

Part of standard construction practice prior to wire installation would involve measuring the resistance of tower footings and installation of counterpoise (grounds) as needed. To determine if a tower would require counterpoise, ground resistance measurements would be taken at towers sites after the installation of the foundations and structures. The measurements would be evaluated to determine the numbers and locations of structures requiring counterpoise. If the resistance to remote earth for each transmission tower is greater than 10 ohms, counterpoise (grounds) would be installed to lower the resistance to 10 ohms or less. Counterpoise would consist of a bare copper-clad or galvanized steel cable buried a minimum of 12 inches deep, extending horizontally from one or more tower legs for approximately 200 feet. Typical counterpoise installation would include two installations per structure on opposite tower legs. Four installations per tower could be required in certain circumstances.

In addition to counterpoise installation, standard grounding practices during construction would include both temporary and permanent grounding of equipment and structures, such as fences or pipelines, as necessary to reduce any potential magnetically induced voltages to harmless levels. Such practices could include electrical isolation of equipment or structures and the installation of grounding wires.

1.1.11 Switching Station Tie-in

At the proposed Haskell Canyon Switching Station, the transmission lines would be connected into and out of the switching station through dedicated station structures within the switching station, commonly referred to as "bus."

1.2 UPKEEP OF CONSTRUCTION SITES

Construction sites, material storage yards, and access roads would be kept in an orderly condition throughout the construction period. Refuse and trash would be removed from the sites and disposed of in an approved manner. Oils and fuels would not be dumped along the line. Oils or chemicals would be hauled to a disposal facility authorized to accept such materials. No open burning of construction trash would occur without agency approval.

Microtrash would be cleaned daily from all work areas within known California condor habitat. Microtrash is a term used to describe small bits of debris like bottle caps, rags, screws, bolts, wires, glass, and other materials found in condor habitat.

1.3 HAZARDOUS MATERIALS WITHIN THE PROJECT AREA

Petroleum products such as gasoline, diesel fuel, helicopter fuel, crankcase oil, lubricants, and cleaning solvents would be present within the Project area during construction. These products would be used to fuel, lubricate, and clean vehicles and equipment. These products would be containerized by fuel trucks or by approved containers. When not in use, hazardous materials would be properly stored to prevent drainage or accidents.

Hazardous materials would not be drained onto the ground or into streams or drainage areas. Totally enclosed containment shall be provided for all trash. All construction waste including trash and litter, garbage, other solid waste, petroleum products, and other potentially hazardous materials would be removed to a disposal facility authorized to accept such materials.

All construction, operation, and maintenance activities would comply with all applicable federal, state, and local laws and regulations regarding the use of hazardous substances.

The construction or maintenance crew foreman would insure that all applicable laws are obeyed. In addition, an on-site inspector would be present during construction to make sure that all hazardous materials are used and stored properly. A health and safety plan would be developed as part of the COM Plan and POD during the engineering and preconstruction phase of the Project.

1.4 SITE RECLAMATION

The ROW, including temporary construction sites, and any temporary ground disturbance outside of the ROW that may have been caused during or due to the construction of the Project (e.g., temporary access roads, staging sites, assembly yards) would be restored as required by the property owner or land management agency. All practical means would be used to restore the land to its original contour and to restore natural drainage patterns along the ROW. Because revegetation would be difficult in many areas of the Project where precipitation is minimal, it would be important to minimize disturbance during construction. All practical means would be used to increase the chances of vegetation reestablishment in disturbed areas.

The total construction period would be approximately two years. The COM Plan that would be completed during the engineering and preconstruction phase of the Project would address specific site reclamation of all disturbed areas.

1.5 FIRE PROTECTION

A Fire Management Plan would be developed for the Project and all applicable fire laws and regulations would be observed during the construction period. All personnel would be advised of their responsibilities under the applicable fire laws and regulations, including taking practical measures to report and suppress fires.

1.6 CONSTRUCTION MONITORING

An approved compliance program would be developed to address mitigation requirements associated with the avoidance of sensitive plant and animal species, cultural sites, or other sensitive features located

within or adjacent to the Project. Prior to construction, these measures will be described in detail and included in the POD.

1.7 THREE-CIRCUIT TOWER MITIGATION

A temporary transmission line would be constructed to keep the BR-RIN circuit energized during construction of the three-circuit towers. After the temporary line is constructed, the existing BR-RIN single-circuit towers would be removed to allow the new three-circuit towers to be constructed within the existing ROW. Once construction of the three-circuit towers is completed, the temporary transmission line would be removed.

The temporary transmission line would be 7.5 miles long and would consist of wood and steel single poles with an average height of 95 feet, a 3-foot by 3-foot footprint, and an average of eight poles per mile. Construction would occur within a temporary 80- to 100-foot ROW. Refer to Table 4 for specifications and to Table 5 for ground disturbance estimates. The majority of the temporary transmission line would be constructed along San Francisquito Road. Portions would also be constructed along Elizabeth Lake Road and Johnson Road. Pole placement would be adjacent to public roadways wherever possible. If necessary, temporary ROW on private property would be needed where poles could not be placed within public road ROW. The majority of poles would be direct-embedded when set in place and would not require a permanent foundation. Where additional strength is necessary at larger angle points, steel poles would be required, which could require an excavation approximately 6 feet in diameter by 20 feet deep to accommodate the concrete pier foundation that would be cast in place. Once all the poles have been constructed and the conductor installed, the existing BR-RIN circuit would be connected into the temporary line and energized. The construction would require establishment of a staging area, work areas around poles, and pull and tension sites. Access to pole sites and pull and tension sites would be from the adjacent roadways.

Approximately seven miles of the existing BR-RIN single-circuit towers would be removed, with existing ROW utilized to access the existing towers. The new three-circuit towers would be placed within the existing ROW, utilizing existing access roads. Helicopter Mitigation, as described in this section below, would be applied in steeper terrain crossing the Angeles National Forest if additional access is required. If additional access roads, considered to be longer than 300 feet, are necessary, specific locations and construction method (either helicopter or conventional) would be coordinated with the USFS. The new three-circuit tower would require a 25-foot by 30-foot structure footprint and an average of seven structures per mile; the average structure height would be 170 feet, with a maximum tower-to-tower span length of 780 feet. Structures would be installed in the same locations as the existing BR-RIN structures within the limits of standard tower design. The construction process for the new three-circuit towers would be the same as the double-circuit towers discussed above. After completion of construction of the three-circuit towers, the temporary transmission line would be removed and all temporary staging and work area land disturbances would be restored as close to previous conditions as possible and revegetated as required. Restoration practices would be consistent with Section 1.11 Decommissioning of Transmission Lines.

TABLE 4. THREE-CIRCUIT TOWER SPECIFICATIONS

Tower Placement Details	Specifications	
	Triple-Circuit	Temporary Transmission Line
ROW acquisition	None (within existing)	80-100 ft
Structures per Mile	7	8
Average span length	750 ft	650 ft

Tower Placement Details	Specifications	
	Triple-Circuit	Temporary Transmission Line
Average height (ft)		
Ground to lowest attachment	120	60
Upper body height	50	45
Overall tower height	170	105
Typical range of heights of new towers	150 - 180 ft.	95 - 105 ft.

1.8 HELICOPTER MITIGATION

The following sites and ground disturbing construction activities would be required to construct the new transmission line within the identified helicopter construction areas: portable landing pads, helicopter fly yards/staging areas and associated temporary access roads, tower structure vegetation clearing, guard structures at major crossings, and access road pullouts. Refer to Table 5 for ground disturbance estimates for the Helicopter Mitigation.

The transmission line materials (tower steel, conductor reels, structure hardware, etc.) would be delivered by truck to the helicopter fly yards/staging areas. Vegetation clearing may be required at these sites to ensure safe working conditions. The fly yards/staging areas would serve as helicopter support yards for fueling and maintenance, as well as for the transport of materials and personnel. Towers may also be assembled in sections at these yards prior to delivery to the tower sites. Heavy lift helicopters would then fly the towers from the yards to the tower sites.

Portable landing pads would be located at each tower site. These pads would allow helicopters to load and unload personnel, tools, and equipment necessary for construction of foundations and assembly of tower structures. Helicopter-constructed towers that would not be in close proximity to existing access roads would utilize micropile foundations. For each tower leg, micropile foundations would use a group of three to eight 6- to 9-inch diameter casings that would be drilled and grouted into the ground. The exposed portion of the pile group would be encased in a reinforced concrete cap from the top of the casings to a depth anywhere from one to eight feet below the ground surface, depending on the terrain. Figure 5 illustrates the plan view and sections of a micropile foundation.

TOP VIEW

Conductor installation would proceed as for double-circuit tower installation. The equipment necessary for conductor installation would be large, heavy construction equipment that could only be brought in by truck. Some NFS roads could need maintenance or improvement to allow pulling and tensioning, but no new access or spur roads would be created for conductor installation on the helicopter-constructed towers.

Information based on LADWP and POWER Engineers, Inc. estimates. Actual disturbance areas may be smaller based on final engineering design.

---

[1] For slopes over 10% (ground disturbance categories 4-6), site dimensions would be 200 x 250 ft. (1.2 acres) and have an average disturbance of 5.8 acres per mile.

[2] For slopes over 10% (ground disturbance categories 4-6), sites would be every 2 miles and have an average disturbance of 1.2 acres per mile.

[3] Access and spur road disturbances included in Table 1.

[4] Ibid.

THIS PAGE INTENTIONALLY LEFT BLANK

1.9 OPERATION OF TRANSMISSION LINES

The nominal voltage for the BRRTP transmission line would be 230 kV AC. There may be minor variations of up to five percent above the nominal level depending upon load flow.

1.9.1 Permitted Uses

After the transmission line has been energized, land uses that are compatible with safety regulations (such as agriculture and grazing) would be permitted in and adjacent to the right-of-way. Incompatible land uses within the right-of-way include construction and maintenance of inhabited dwellings, and any use requiring changes in surface elevation that would affect electrical clearances of existing or planned facilities.

Land uses on public lands that comply with local regulations would be permitted adjacent to or within the ROW, with require approval from the appropriate agency. Permission to use the ROW on private lands would have to be obtained from the utility owning the transmission line.

1.9.2 Safety

Safety is a primary concern in the design of this 230 kV transmission line. The AC transmission line would be protected with power circuit breakers and related line relay protection equipment. If conductor failure occurs, power would be automatically removed from the line. Lightning protection would be provided by overhead ground wires along the line. Electrical equipment and fencing at the switching station would be grounded. All fences, metal gates, pipelines, and other metal components that cross or are within the transmission line ROW would be grounded to prevent electrical shock. If applicable, grounding outside of the ROW may also occur.

1.10 MAINTENANCE OF TRANSMISSION LINES

The 230 kV transmission line would be inspected several times annually by both ground and air patrols. Maintenance would be performed as needed. When access is required for non-emergency maintenance and repairs, LADWP would adhere to the same precautions and procedures that were taken during the original construction.

Emergency maintenance would involve prompt movement of repair crews to repair or replace any damaged equipment or infrastructure. Crews would be instructed to protect crops, plants, wildlife, and other resources of significance. Restoration procedures following completion of repair work would be those prescribed for project implementation construction. The comfort and safety of local residents would be provided for by limiting noise, dust, and the danger caused by maintenance vehicle traffic. Details would be provided in the COM Plan and POD prior to line construction.

1.10.1 Vegetation Management

Vegetation management along the transmission line ROW would be required by the North American Reliability Council (NERC). In compliance with the NERC's Standard FAC-003-l, LADWP would prepare a Vegetation Management Plan for the BRRTP. The Vegetation Management Plan would be included in the COM Plan to be completed prior to the issuance of a Notice to Proceed from the USFS and BLM. Vegetation management would consist of routine tree trimming to maintain the required minimum 10-foot clearance from conductors to vegetation (California Public Resources Code [PRC] 4293); clearance of flammable brush vegetation within a 10-foot radius around the base of transmission line towers in accordance with California PRC 4292; and clearance immediately adjacent to access roads to permit adequate access to the facilities.

1.10.2 Access Road Maintenance

Ongoing access road maintenance would be conducted in accordance with existing or new road authorizations issued to LADWP. Access road maintenance consists of those activities necessary to allow continued access to the ROW and/or each tower structure. These activities may include grading, and maintenance of drainage systems, bridges, culverts, fences, gates and signs. Motor graders, backhoes, dump trucks and pickups are used to maintain access roads.

1.11 DECOMMISSIONING OF TRANSMISSION LINES

At the end of the useful life of the proposed Project, if the facility were no longer required, or if extension of the authorizations were not granted by federal land agencies at the time they expired, the transmission line would be abandoned. Subsequently, conductors, insulators and hardware would be dismantled and removed from the ROW. Tower structures would be removed and foundations broken off below ground surface.

If the line and associated ROW are abandoned at some future date, the ROW would be available for the same uses that existed prior to construction of the Project. Following abandonment and removal of the transmission line from the ROW, any areas disturbed to dismantle the line would be restored and rehabilitated as near as possible to their original condition.

2.0 ADDITION OF NEW 230 KV CIRCUIT

Between the proposed Haskell Canyon Switching Station and the existing Castaic Power Plant, LADWP proposes the addition of 12 miles of a new 230 kV transmission circuit onto existing Castaic – Olive 230 kV Transmission Line structures (towers 1-1 through 12-1). This new circuit would be called Castaic – Haskell Canyon #4 and would utilize the same conductor (2,156 kcmil “Bluebird” ACSS/AW) as that proposed for the new 230 kV transmission line between Barren Ridge and Haskell Canyon Switching Stations.

The addition of a new circuit on existing towers would require many of the same activities of a new transmission line (surveying of ROW, rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, and cleanup). However, all work would be within existing ROW and no new towers would be constructed. Some towers may need to be modified or reinforced to carry the additional weight of the new conductor. Specific towers requiring reinforcement would be determined following detailed design of the Project. Tower reinforcement would not alter the general design or the location of the structures. This process would generally include reinforced foundations or steel member replacements.

3.0 RECONDUCTORING

LADWP proposes the reconductoring of 76 miles of the existing BR-RIN 230 kV transmission line with larger conductors between the Barren Ridge Switching Station and Rinaldi Substation (towers 176-1 through 251-1). The existing conductors (954/ 2,312 kcmil) would be replaced with a new 1,433.6 kcmil “Merrimack” ACSS/TW/HS conductor. The new conductor would have a larger diameter that allows for greater electrical capacity.

The upgrade of the existing BR-RIN would also require many of the same activities of the new transmission line (surveying of ROW, rehabilitation of existing access and spur roads, clearing of ROW, conductor installation, and cleanup). Removal of the existing conductor would be used to string a pulling line, and this line would then be used to pull in the new conductor. All work would remain within the existing 250-foot-wide ROW, with no additional ROW required. Some of the towers would need to be

modified, replaced, and/or have foundations reinforced or replaced to carry the additional weight of the new heavier conductor.

4.0 NEW HASKELL CANYON SWITCHING STATION

As a component of the BRRTP, LADWP proposes the construction of a new switching station in Haskell Canyon, south of the Angeles National Forest on LADWP-owned property at the convergence of several existing and proposed 230 kV transmission lines (the existing BR-RIN, the proposed double-circuit Barren Ridge-Haskell Canyon, existing Castaic-Northridge, Castaic-Sylmar, Castaic-Olive, and the proposed Castaic to Haskell Canyon).

The station would be approximately 500 feet by 600 feet to accommodate the necessary circuit positions, which are made up of equipment, such as steel support structures, circuit breakers, disconnect switches, and associated equipment, and a relay house and control house containing control and protective relaying equipment. The relay and control houses would each be approximately 30 feet long by 12 feet wide by 10 feet high and constructed of gray concrete block. The station yard would include a paved internal access road approximately 16 feet wide and would be enclosed by chain-link fencing with barbed-wire extension for security. Figure 6 illustrates the preliminary design layout for the station. Figure 7 illustrates the preliminary grading plan for the station.

Necessary pre-construction geotechnical investigation on-site would include six borings by a drill rig to investigate bedrock and soil stability and four cone penetration test locations after site grading to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

Construction of the new Haskell Canyon Switching Station would consist of preconstruction surveys, clearing and grading of access roads, site grading and drainage development, installation of concrete foundations and steel support structures, installation of below- and above-ground electrical conduits for equipment power and control, installation of below- and above-grade grounding conductors, and installation of control and relay houses. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks, and flatbed trailers. Cranes, man-lifts, portable welding units, line trucks, and mechanic trucks would also be required. Construction would require an estimated 12 months with approximately 60 workers.

Site preparation work for the station would involve clearing and grading of access roads, clearing of the switchyard site, the cut and fill grading of the site, and placement and compaction of structural fill that would serve as a base for switching station facilities. The site would be graded to maintain current drainage patterns as much as possible. A 16-foot wide paved road and 100-foot by 100-foot gravel parking area would be required. The yard would be covered with crushed-rock aggregate. Native vegetation would be re-established where possible outside the switchyard fence.

Following site grading and development, reinforced concrete foundations would be installed to support the steel structures and electrical equipment and control facilities. It is estimated that 1,500 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 180 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 120-day working period. Subsequent to the foundation installation, trenches would be dug to facilitate placement of copper conductors for the station grounding mat.

Multiple transmission lines would be terminated into the switching station (i.e., the new and existing Barren Ridge – Haskell and Castaic – Haskell Canyon transmission lines) and would need support and

require the installation of galvanized steel structures. An existing 115 kV transmission line may need to be relocated around the proposed station. High-voltage bus work consisting of aluminum jumpers and tubing would be installed within the station.

PRELIMINARY IMPROVED
ACCESS ROAD SUMMARY:
ROAD LENGTH 3,800 FT
ROAD WIDTH
EXISTING 14 FT
PROPOSED 22 FT
MAXIMUM SLOPE 15 %
MINIMUM CENTERLINE RADIUS OF CURVES 80 FT
NOTES:
THE ALIGNMENT OF THE PROPOSED PAVED ACCESS ROAD FOLLOWS THAT OF THE EXISTING PATROL ROAD.
THE EXISTING ACCESS ROAD WILL NEED TO BE WIDENED AND PAVED TO ALLOW SERVICE VEHICLES ACCESS TO THE PROPOSED STATION. WIDENING THE ROAD WILL REQUIRE ADDITIONAL GRADING AND EARTHWORK.
THE PROPOSED ACCESS ROAD MAY BE SUBJECT TO THE APPROVAL THE LOS ANGELES COUNTY FIRE DEPARTMENT.
THE EARTHWORK QUANTITIES AND CONSTRUCTION COST ESTIMATES LISTED ON SHEET 1 DOES NOT INCLUDE THE CONSTRUCTION OF THE IMPROVED ACCESS ROAD.
IN THIS ALTERNATIVE, THE PROPOSED STATION EXTENDS INTO PRIVATE PROPERTY. RIGHTS TO THIS PRIVATE PROPERTY MUST BE ACQUIRED BY LADWP.
PLEASE NOTE THAT THIS DESIGN IS PRELIMINARY. THE TOPOGRAPHY, PROPRETY LINES, PROJECT LIMITS AND DESIGN VARIABLES ARE APPROXIMATE AND THUS SUBJECT TO CHANGE. A NUMBER OF REMAINING ENGINEERING AND ENVIRONMENTAL ISSUES MUST STILL BE RESOLVED. THIS EXHIBIT, AND CORRESPONDING CONSTRUCTION COST ESTIMATE, ARE FOR PRELIMINARY SITE EVALUATION PURPOSES ONLY.

5.0 EXPANSION OF BARREN RIDGE SWITCHING STATION

LADWP proposes expansion of the existing Barren Ridge Switching Station to the east side by 235 feet by 500 feet, for a total station size of 485 feet by 500 feet (approximately 5.6 acres). The expansion area of the station would include electrical structures and equipment for the addition of transmission lines, a material staging area, roadway within the station, and drainage area. Figure 8 illustrates the preliminary design layout for the station.

Expansion of the existing switching station would be very similar to the construction of the Haskell Canyon Switching Station as described above. Expansion would consist of preconstruction surveys, site preparation and grading, installation of reinforced concrete foundations, installation of electrical conduits for equipment power and control, and installation of structures and equipment.

Necessary pre-construction geotechnical on-site investigation would include two test pits excavated by a backhoe to investigate soil density and settlement, and four cone penetration test locations on-site to determine friction resistance for piers. The cone penetration test rig would be a small truck with a hydraulic ram assembly mounted on the back, which is used to push a 2.5-inch diameter cone into the ground to a depth up to 50 feet. Existing roads would be used to access the site.

It is estimated that 700 cubic yards of concrete would need to be delivered to the switching station site for the foundations. Foundation work would require approximately 80 trips to the site by 40-ton, 10-yard capacity concrete trucks over a 90-day working period. Equipment required for station construction would include graders and excavators, backhoes, drill rigs, water trucks, scrapers, sheep's foot compactors, front end loaders, concrete trucks, trucks and flatbed trailers. Cranes, man-lifts, portable welding units, line

trucks, and mechanic trucks would also be required. An estimated 8 months with approximately 60 workers would be required to expand the station.

1.0 INTRODUCTION

The City of Los Angeles Department of Water and Power (LADWP) is proposing the Barren Ridge Renewable Transmission Project (BRRTP or Project) to access clean, renewable resources in the Tehachapi Mountains and Mojave Desert areas, and to improve reliability and upgrade transmission capacity.

LADWP, the US Department of Agriculture, Forest Service (USFS or Forest Service) and the U.S Department of the Interior, Bureau of Land Management (BLM) are preparing a joint Environmental Impact Statement (EIS) / Environmental Impact Report (EIR) for the proposed BRRTP. LADWP is the California Environmental Quality Act (CEQA) Lead Agency, while the USFS and BLM are the federal Co-Lead Agencies under the National Environmental Policy Act (NEPA). An EIS/EIR is an informational disclosure document used to inform agency decision makers and the public of the potential significant environmental effects of a project, identify possible ways to eliminate or minimize the potential significant effects, and describe reasonable alternatives to the Proposed Action /Project.

The purpose of the water resources and hydrology study is to inventory existing water resources and assess the potential impacts to water resources of each of the proposed transmission line alternative corridors, proposed switching station, and expansion of the existing switching station. The water resource environmental analysis will:

- present the regulatory framework
- provide an overview of the technical methodology used in collecting baseline conditions and evaluating impacts
- examine the affected environment within the study corridors and vicinity, where appropriate
- describe the potential impacts on water resources resulting from construction and operation of the Project
- evaluate the level of potential impacts based upon National Environmental Policy Act (NEPA)/California Environmental Quality Act (CEQA) criteria
- present specifically recommended mitigation measures to minimize potential impacts.

Portions of the BRRTP Alternatives would traverse the western section of the Angeles National Forest (ANF or Forest), and have the potential to adversely affect the watersheds through which they cross. Adverse effects may result from vegetation clearance and general ground disturbance during construction of the Project, as well as leaks or spills of oils or other hazardous fluids from construction and maintenance vehicles or equipment. Specifically, Forest watersheds could be adversely affected by sedimentation and erosion resulting from construction activities. This report contains an inventory of water resources within affected Forest watersheds, and evaluates the potential for Project-related erosion and related changes in hydrology. Potential adverse effects are analyzed for each BRRTP Alternative.

2.0 PURPOSE AND SCOPE

The purpose of this report is to identify water resources potentially affected by the Alternatives of the BRRTP, and to analyze effects of construction and operation of the Project on erosion and sedimentation. The scope of this report is limited to those portions of each BRRTP Alternative that would be located within the Angeles National Forest.

This report is supplemental to the complete Water Resources Technical Report, and has been prepared at the request of Mr. Paul Gregory, ANF Hydrologist.

2.1 ISSUES

This report will focus on identifying and analyzing BRRTP effects on water resources within HUC 12 (6th Level) watersheds. In addition to analyzing potential effects on existing water resources, Mr. Gregory requested a Revised Universal Soil Loss Equation (RUSLE) analysis (Appendix A of this report) to predict the rate of erosion that would potentially result from construction of the BRRTP within the Forest. Mr. Gregory also requested a statistical analysis of 6th level watersheds within the ANF that would be affected by the BRRTP Alternatives, to predict peak flow within the watersheds pre- and post-construction.

3.0 BACKGROUND

3.1 GENERAL DESCRIPTION

The BRRTP would be located within the western section of the Angeles National Forest, in the Santa Clara/Mojave Rivers Ranger District. The Project area includes 16 HUC 12 6th level watersheds, 12 of which would be affected by BRRTP Alternatives, as described in this report. These affected watersheds are Liebre Gulch-Piru Creek, Upper Castaic Creek, Fish Creek-Piru Creek, Lake Piru-Piru Creek, Lower Castaic Creek, Elizabeth Lake, Elizabeth Lake Canyon, San Francisquito Canyon, Lower Bouquet Canyon, Agua Dulce Canyon, Mint Canyon, and Upper Bouquet Canyon (Figure 1).

The BRRTP is located in portions of Township 05N Range 16W Sections 20, 21, 22, 25, 26, and 27; Township 05N Range 17W Section 4; Township 06N Range 17W Sections 6, 7, 8, 17, 20, 21, 28, 33, and 34; Township 07N Range 17W Sections 19, 30, and 31; Township 07N Range 18W Sections 2, 11, 12, 13, and 24; and Township 08N Range 18W Section 35, in Los Angeles County, California.

Land Use Zones have been designated within the ANF to identify appropriate uses that are consistent with the Forest Land Management Plan (USFS 2005). Some Zones have restrictions that may affect projects proposed within them.

One Wild and Scenic River, and one eligible Wild and Scenic River are within the Project area. Piru Creek, a designated Wild and Scenic River, is located approximately two miles west of Alternative 1. San Francisquito Canyon Creek, which is eligible for Wild and Scenic River designation, is located in the center of the Project area, and is generally paralleled by Alternatives 2 and 2a.

Three Critical Biological Areas occur in the Project area. One is located in San Francisquito Canyon, and is designated Critical Habitat for the California red-legged frog (*Rana draytonii*). The remaining two Critical Biological Areas are located in Castaic Creek and Fish Creek, and host Critical Habitat for the arroyo toad (*Anaxyrus californicus*).

Riparian Conservation Areas (RCAs) combine the ecologic concerns of riparian ecosystems with the hydrologic concerns of floodplains and streamside slopes. RCAs have been established within the Angeles National Forest to protect, maintain, or improve water quality, site productivity, channel stability, riparian vegetation, and riparian-dependent species and habitats. RCAs are associated with many streams within the Forest, including West Fork Liebre Gulch, Liebre Gulch, San Francisquito Canyon, Dry Canyon, Bee Canyon, Pettinger Canyon, Munz Canyon, Mint Canyon, and multiple unnamed streams.

The Project area is located in the Transverse Ranges Geomorphic Province, which is characterized by east-west trending mountain ranges and fault systems. The province is bounded on the northeast by the San Andreas Fault, and extends west and south from the study area. The Project area is underlain by Tertiary and pre-Tertiary rock formations, with the exception of canyon bottoms and other drainage areas comprised of alluvium. Soil erosion along the BRRTP Alternatives ranges from Slight to Very Severe.

The climate of the BRRTP area is Mediterranean, with warm, dry summers and cool, wet winters. Most precipitation occurs between November and March, when storm systems from the north Pacific approach the area from the west or southwest, often producing precipitation simultaneously throughout the area. The orographic effect often results in intense precipitation along and within the San Gabriel Mountains. Annual precipitation averages 14.32 inches at Elizabeth Lake, with much falling as snow; in the higher elevations, precipitation averages up to 40 inches, with over 95% falling as snow. Maximum daily temperatures vary with elevation, but range from the 90s during the summer months to the 30s during the winter months (Western Regional Climate Center 2011).

4.0 AFFECTED ENVIRONMENT

The affected environment of the BRRTP includes 12 6th level watersheds, numerous intermittent streams and RCAs, several National Wetland Inventory (NWI) wetlands, and several 100-year Federal Emergency Management Agency (FEMA) floodplains. In addition, the affected environment includes one Critical Biological Area; the Critical Biological Area within San Francisquito Canyon would be closely paralleled by BRRTP Alternatives 2 and 2a.

The affected area includes the drainages in the Liebre Gulch-Piru Creek, Upper Castaic Creek, Fish Creek-Piru Creek, Lake Piru-Piru Creek, Lower Castaic Creek, San Francisquito Canyon, Lower Bouquet Canyon, Elizabeth Lake, Elizabeth Lake Canyon, Agua Dulce Canyon, Mint Canyon, and Upper Bouquet Canyon watersheds. Most of these watersheds lie entirely within the ANF, Santa Clara/Mojave Rivers Ranger District. Table 1 shows names and acreages of these watersheds.

TABLE 1. WATERSHEDS IN THE BRRTP AREA.

Watershed	Watershed Number	Watershed Acreage
Liebre Gulch-Piru Creek	180701020509	14,139
Upper Castaic Creek	180701020303	24,063
Fish Creek-Piru Creek	180701020602	25,781
Lake Piru-Piru Creek	180701020603	34,246
Lower Castaic Creek	180701020306	30,296
San Francisquito Canyon	180701020402	31,695
Lower Bouquet Canyon	180701020202	22,075
Elizabeth Lake	180701020301	11,411
Elizabeth Lake Canyon	180701020304	34,504
Agua Dulce Canyon	180701020104	18,814
Mint Canyon	180701020106	18,664
Upper Bouquet Canyon	180701020201	24,517

The mountains in the BRRTP area generally range from steep to very steep, with summits that are sharp or rounded. Steeper slopes are often barren of vegetations and show evidence of erosion. Canyons are often narrow, with steep, rocky sides and littered with many rocks and boulders. Water is present year-round only in the larger streams, such as San Francisquito Canyon (USFS 2005).

Vegetation in this area is dominated by mixed chaparral series with a sparse mixture of oak, riparian, and pine forests, decreasing in density in the lower elevations. Dense areas of chaparral provide excellent ground cover and serve to stabilize slopes, minimize soil erosion, peak storm flows, and sedimentation within and from the watersheds. A layer of forest duff and organic litter provide ground cover which slows stormwater runoff on slopes, protects soils from erosion, and assists with water infiltration.

Floodplains in the Project area tend to be contained within the walls of the drainages, only expanding in the lower reaches near the stream outlet. Heavy storms may scour the stream channel and floodplain bare of vegetation, leaving behind disturbed soil conditions that are prime for colonization by non-native plant species that compete with native plants for groundwater, which often occurs nearer the surface in floodplains.

The National Wetlands Inventory maps approximate locations of wetlands one acre or larger based on aerial photographs and remote sensing techniques. NWI wetlands may or may not be jurisdictional based on the 1987 U.S. Army Corps of Engineers Wetlands Delineation Manual.

The Pacific Southwest Region of the USFS analyzed all watersheds in California and assigned watershed condition ratings to each watershed. Condition ratings are based on diagnostic indicators that ultimately yield an assessment of the condition of each watershed based on their geomorphic, hydrologic, and biological integrity relative to their natural condition, as judged by Forest Service geologists, hydrologists, and biologists (USFS 2000). Ratings and their descriptions are shown in Table 2 below.

TABLE 2. CONDITION CATEGORIES FOR WATERSHEDS IN THE USFS PACIFIC SOUTHWEST REGION.

Category	Description
Category Condition I	Watersheds that are currently exhibiting high geomorphic, hydrologic, and biotic integrity relative to their natural potential condition and exhibit a stable drainage network. Physical and biological conditions suggest that aquatic and riparian systems are predominantly functional in terms of supporting dependent species and beneficial uses of water. The risks of management induced disturbance have not been expressed or resulted in significant alteration of geomorphic, hydrologic, and biotic processes.
Category Condition II	Watersheds that are currently exhibiting moderate geomorphic, hydrologic, and biotic integrity relative to its natural potential condition and portions of these watersheds exhibit an unstable drainage network. Physical and biological conditions suggest that aquatic and riparian systems are at risk in being able to support dependent species and retain beneficial uses of water. The risks of management induced disturbance are variable and effects have partially been expressed or have resulted in localized alteration of geomorphic, hydrologic, and biotic processes.
Category Condition III	Watersheds that are currently exhibiting low geomorphic, hydrologic, and biotic integrity relative to their natural potential condition and a majority of the drainage network is unstable. Physical and biological conditions suggest that riparian and aquatic systems do not support dependent species nor beneficial uses of water. The risks of management induced disturbance are high; they have been fully expressed and/or have resulted in deterioration of geomorphic, hydrologic, and/or biotic processes.

The California State Water Resources Control Board (SWRCB) requires individual Regional Water Quality Control Boards (RWQCBs) to develop Basin Plans (water quality control plans) designed to preserve and enhance water quality and protect the beneficial uses of all Regional waters. Specifically, Basin Plans designate beneficial uses for surface waters and groundwater, set narrative and numerical objectives that must be attainted or maintained to protect the designated beneficial uses and conform to the States antidegradation policy, and describe implementation programs to protect all waters in the Regions. In addition, Basin Plans incorporate by reference all applicable State and Regional Board plans and policies, and other pertinent water quality policies and regulations. Within the ANF, the BRRTP is under the jurisdiction of the Basin Plan of the Los Angeles Regional Water Quality Control Board.

Section 303(d) unites the water quality management strategies of the federal Clean Water Act (CWA). Section 303(d) requires that states make a list of waters that exceed the minimum level of pollutants put in place by the CWA. For waters on this list the states must develop total maximum daily loads (TMDLs), which account for all sources of the pollutants that caused the water to be listed. The TMDLs must account for contributions from both point sources and nonpoint sources, as defined by Section 402 of the CWA. In California, the SWRCB has interpreted state law to require that implementation of TMDLs be addressed when incorporated into Basin Plans (water quality control plans).

Within the ANF, the BRRTP Alternatives would cross two groundwater basins and one sub-basin. These basins are described in California's Groundwater Bulletin 118 and summarized below.

- **Antelope Valley Groundwater Basin (Groundwater Basin Number 6-44).** The Antelope Valley Groundwater Basin drains a surface area of approximately 1,010,000 acres (1,580 square miles). The basin underlies an extensive alluvial valley in the western Mojave Desert, and is bounded on the northwest by the Garlock fault zone at the base of the Tehachapi Mountains, on the southwest by the San Andreas fault zone at the northern base of the San Gabriel Mountains, on the east by ridges, buttes, and low hills that form a surface and groundwater drainage divide, and on the north by the Fremont Groundwater Basin described above.

  The primary aquifers in this basin are unconsolidated alluvial and lacustrine deposits from the Pleistocene and Holocene, forming an upper aquifer and a lower aquifer. The upper aquifer is the primary source of groundwater in the Antelope Valley, and is generally unconfined. The basin comprises three large sediment-filled structural sub-basins separated by extensively faulted, elevated bedrock. Numerous faults displace the water table and impede groundwater flow within the basin.

Total storage capacity of the Antelope Valley Groundwater Basin is between 68,000,000 and 70,000,000 af, except for an area of the basin where the groundwater is between 20 and 220 feet in depth. In that area, the storage capacity is approximately 5,400,000 af. Between 1975 and 1998, groundwater in this basin ranged from an increase of 84 feet to a decrease of 66 feet. The area of the basin that experienced a decrease in groundwater depth is along the State Route 14 corridor from Palmdale to Rosamond. In the vicinity of the study corridors that cross the Antelope Valley Groundwater Basin, recent depth-to-water measurements in USGS wells ranged between 152.83 feet and 390.79 feet (DWR 2003).

- **Acton Valley Groundwater Basin (Groundwater Basin Number 4-5).** The Acton Valley Groundwater Basin drains a surface area of approximately 8,270 acres (12.9 square miles). The basin is unconfined, and groundwater is found in alluvium and stream terrace deposits. The basin is bounded by the Sierra Pelona on the north, and the San Gabriel Mountains on the south, east, and west.

  Groundwater in the basin is unconfined. The water-bearing formations in this basin are Holocene alluvial deposits and Pleistocene stream terrace deposits. The alluvial deposits reach a maximum thickness of approximately 225 feet in the Santa Clara River channel near the community of Acton, and thin out east and west of this area. The stream terrace deposits are found on low-lying flanks of the foothills and upper reaches of the tributaries of the Santa Clara River, and reach a maximum thickness of approximately 210 feet north of Acton.

  Total storage capacity of the Acton Valley Groundwater Basin is approximately 40,000 af. Groundwater levels declined from the 1950s through the mid-1970s; groundwater levels increased from the late 1970s through the mid-1980s, but began declining again. Current depth-to-water measurements were unavailable for the Acton Valley Groundwater Basin (DWR 2003).

- **Santa Clara River Valley East Sub-basin (Groundwater Basin Number 4-4.07).** The Santa Clara River Valley East Sub-basin drains a surface area of approximately 66,200 acres (103 square miles). The basin is bounded on the north by the Piru Mountains, on the west by impervious rocks of the Modelo and Saugus Formations and a constriction in the alluvium, on the south by the Santa Susana Mountains and the San Gabriel Mountains, and on the east by the San Gabriel Mountains.

  Groundwater in the sub-basin is found in Holocene alluvium, Pleistocene terrace deposits, and in the late Pliocene to early Pleistocene Saugus Formation. Groundwater is generally unconfined in the alluvium, but may be confined, semi-confined, or unconfined in the Saugus Formation. Alluvium deposits reach a maximum thickness of approximately 240 feet below the Santa Clara River channel and thin laterally away from the channel, and east and west of the community of Acton. The terrace deposits generally lie above the water table, and are found on the low-lying flanks of the foothills and upper reaches of the Santa Clara River tributaries. These deposits reach thicknesses of up to 200 feet near Saugus, Agua Dulce, and Acton. The Saugus Formation is up to 8,500 feet thick, and is not widely utilized as a groundwater source for municipal and agricultural uses, as the water can be brackish. The maximum depth to the base of fresh water ranges from 1,500 feet northeast of the San Gabriel Fault to 5,500 feet between the San Gabriel Fault and the Holser Fault.

Although the Saugus Formation is displaced by both the San Gabriel and Holser Faults, groundwater movement in the Formation has not been affected. The water-bearing alluvial deposits have not been affected by fault displacement.

Total storage capacity of the sub-basin is approximately 240,000 af in the alluvial aquifer, and approximately 1,650 af in the Saugus Formation. Between 1970 and 2000, groundwater levels were relatively stable with depth-to-water levels in the alluvial aquifer measuring from between approximately 13 feet to 37 feet in the western portion of the sub-basin, 10 feet to 50 feet in the central portion, and 15 feet to 100 feet in the eastern portions of the sub-basin. In the Saugus Formation, depth-to-water levels have also remained stable. In the vicinity of the study corridors adjacent to the Santa Clara River Valley East Sub-basin, recent depth-to-water measurements in USGS wells ranged between 9.60 feet and 10.20 feet (DWR 2003).

4.1 WATER RESOURCE INVENTORY

The goal of the water resource inventory was to identify, map, describe, and document existing water resources within the affected watersheds of each BRRTP Alternative. Detailed data inventories were compiled to facilitate the assessment of potential water resource effects resulting from construction and operation of the Project.

Initially, base maps of the Project area were prepared at a scale of 1:12,000. Water resource data collected from federal and state databases were reviewed, refined, and updated. Existing maps from the United States Geological Survey (USGS), National Wetland Inventory (NWI), and Federal Emergency Management Agency (FEMA) were collected and included in the inventory, as appropriate. These data were compiled and mapped utilizing a geographic information system (GIS).

The study used National Agriculture Imagery Program (NAIP) 2005 color aerial photography, and national, state, and local agency GIS data layers to identify and more accurately assess surface land uses and land cover types.

A description of water resources was divided by affected watershed. Existing water resources were identified within the Alternative study corridor to present an overview of the water resources that would potentially be affected by the transmission line alternatives.

4.2 WATERSHEDS

4.2.1. Liebre Gulch-Piru Creek Watershed (HUC 180701020509)

The Liebre Gulch-Piru Creek Watershed is located in the Castaic Unit of the ANF, and has a Summary Watershed Condition Category rating of I. This watershed drains approximately 14,139 acres; drainages in this watershed include those in West Fork Liebre Gulch, Liebre Gulch, and Posey Canyon, all of which drain into Pyramid Lake. Pyramid Lake and the southernmost reach of West Fork Liebre Gulch have associated FEMA 100-year floodplains.

The NWI has mapped two wetlands within this watershed: Pyramid Lake has been mapped as a lacustrine wetland (L1UB); and a small 0.4-mile portion of West Fork Liebre Gulch immediately north of Interstate 5 has been mapped as Other Wetland.

Within the ANF, many of the larger drainages and their tributaries have associated RCAs; in the ANF portion of the Liebre Gulch-Piru Creek Watershed, there are approximately 39 RCAs.

Beneficial uses of surface waters in this watershed include Municipal and Domestic Supply, Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Hydropower Generation, Water Contact Recreation, Non-contact Water Recreation, Warm Freshwater Habitat, Cold Freshwater Habitat, Wildlife Habitat, Rare, Threatened, or Endangered Species, Spawning, Reproduction, and/or Early Development, and Wetland Habitat.

The Liebre Gulch-Piru Creek Watershed does not lie above a defined groundwater basin.

BRRTP Alternative 1 would cross the ANF section of the Liebre Gulch-Piru Creek Watershed from mile marker 58.1 to 62.9, at mile marker 64.2, and from mile marker 64.6 to 64.8. Ground slope in the vicinity of Alternative 1 typically ranges from 20 percent to 30 percent; however, in many areas, slope is greater than 30 percent.

4.2.2. Upper Castaic Creek Watershed (HUC 180701020303)

The Upper Castaic Creek Watershed is located in the San Francisquito Unit of the ANF, and has a Summary Watershed Condition Category rating of III. This watershed drains approximately 24,063 acres; drainages within this watershed include those in Trough Canyon, Cold Canyon, Cienega Canyon, Pine Canyon, Bear Canyon, and Redrock Canyon, as well as Falls Creek, Castaic Creek, and Salt Creek. FEMA has not mapped 100-year floodplains associated with these drainages.

Palustrine forested (PFO) wetlands, palustrine scrub-shrub (PSS) wetlands, and "other" wetlands have been mapped by the NWI in and adjacent to Cienega Canyon (T07N R17W Sections 15, 22, and 27). Additional PFO wetlands are mapped in Section 14 NW, in Section 12 SW at the northern end of Bear Canyon, and in Section 10 SW.

There is a Critical Biological Area located in Castaic Creek that contains designated Critical Habitat for arroyo toad.

Much of Castaic Creek and many of its tributaries have associated RCAs. In the Upper Castaic Creek Watershed there are approximately 55 RCAs.

Beneficial uses of surface waters in this watershed include Municipal and Domestic Supply, Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Water Contact Recreation, Non-contact Water Recreation, Commercial and Sport Fishing, Warm Freshwater Habitat, Wildlife Habitat, and Rare, Threatened, or Endangered Species.

The southern portion of the Upper Castaic Creek Watershed lies above the Santa Clara River Valley East Groundwater Sub-basin.

BRRTP Alternative 1 would cross through the ANF section of the Upper Castaic Creek Watershed from mile marker 62.7 to 64.2, and from mile marker 64.6 to 66.5. Ground slope in the vicinity typically ranges from 20 percent to 30 percent, with many slopes adjacent to Alternative 1 greater than 30 percent.

4.2.3. Fish Creek-Piru Creek Watershed (HUC 180701020602)

The Fish Creek-Piru Creek Watershed is located in the Upper Piru Unit of the ANF, and has a Summary Watershed Condition Category rating of II. This watershed drains approximately 25,781 acres; drainages within this watershed include those in Cherry Canyon, Osito Canyon, Turtle Canyon, Ruby Canyon, and Oak Flats, as well as Piru Creek, North Fork Fish Creek, Fish Creek, and Michael Creek. FEMA has mapped 100-year floodplains associated with Piru Creek from Pyramid Dam to the border of the Los Padres National Forest, a distance of approximately 3.5 miles. Piru Creek is a designated Wild and Scenic River, from 0.5 mile south of Pyramid Dam to the Los Angeles-Ventura Counties border, a distance of 7.5 miles.

The NWI has mapped a number of wetlands within the Fish Creek-Piru Creek watershed, many of which are associated with Piru Creek, which is itself designated a riverine upper perennial (R3) wetland. Other

NWI wetlands associated with Piru Creek are PFO and PSS wetlands. Additional NWI wetlands are located near Halfway Spring Campsite, Cobblestone Springs, both of which are in the Los Padres National Forest. In the ANF, the NWI has mapped a PFO wetland near Oak Flat Spring in T06N R17W Section 19NW.

Fish Creek, Piru Creek, and many of their tributaries have associated RCAs. In the ANF portion of the Fish Creek-Piru Creek Watershed, there are approximately 26 RCAs.

Beneficial uses of surface waters in this watershed include Municipal and Domestic Supply, Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Water Contact Recreation, Non-contact Water Recreation, Warm Freshwater Habitat, Cold Freshwater Habitat, Wildlife Habitat, Rare, Threatened, or Endangered Species, Spawning, Reproduction, and/or Early Development, and Wetland Habitat.

Piru Creek is listed on the 2006 CWA Section 303(d) List of Water Quality Limited Segments Requiring TMDLs as impaired by unhealthy chloride and pH levels.

The Fish Creek-Piru Creek Watershed does not lie above a defined groundwater basin.

BRRTP Alternative 1 would cross through the ANF section of the Fish Creek-Piru Creek Watershed from mile marker 66.0 to 68.5. Ground slope in the vicinity typically ranges from 20 percent to 30 percent, with many slopes adjacent to Alternative 1 greater than 30 percent.

4.2.4. Lake Piru-Piru Creek Watershed (HUC 180701020603)

The Lake Piru-Piru Creek Watershed is located in the Upper Piru Unit of the ANF, and has a Summary Watershed Condition Category rating of II. This watershed drains approximately 34,246 acres; drainages in this watershed include those in Big Oak Flat, Canton Canyon, Santa Felicia Canyon, Devil Canyon, Sharps Canyon, Oak Canyon, Lechler Canyon, Dominguez Canyon, Maple Canyon, and Reasoner Canyon, all of which drain into Lake Piru, which is located on the southern border of the watershed. Only Lake Piru has an associated FEMA 100-year floodplain.

The NWI has mapped the lower reaches of Canton Canyon as an intermittent riverine (R4) wetland. As in the Fish Creek-Piru Creek Watershed, Piru Creek is designated an R3 wetland, with associated PFO and PSS wetlands. The NWI has designated stretches of Reasoner Canyon and Dominguez Canyon as Riparian Forests. A palustrine emergent (PEM) wetland is mapped on the western edge of Lake Piru, below the confluence of the Reasoner Canyon and Dominguez Canyon drainages. Lechter, Santa Felicia, and Devil Canyons have associated PFO wetlands, and the NWI has also mapped a PSS wetland in an unnamed tributary to Santa Felicia Canyon, approximately 0.7 mile east of the Los Angeles-Ventura Counties line.

The drainages in Canton Canyon, Big Oak Flat, and many of their tributaries have associated RCAs. In the ANF portion of the Lake Piru-Piru Creek Watershed, there are approximately 24 RCAs.

Beneficial uses of surface waters in this watershed include Municipal and Domestic Supply, Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Hydropower Generation, Water Contact Recreation, Non-contact Water Recreation, Commercial and Sport Fishing, Warm Freshwater Habitat, Cold Freshwater Habitat, Wildlife Habitat, Rare, Threatened, or Endangered Species, and Spawning, Reproduction, and/or Early Development.

The southeastern portion of the Lake Piru-Piru Creek Watershed lies above the Santa Clara River Valley East Groundwater Sub-basin.

BRRTP Alternative 1 would cross the ANF section of the Lake Piru-Piru Creek Watershed from mile marker 68.3 to 71.5. Ground slope in the vicinity typically ranges from 20 percent to 30 percent, with some slopes greater than 30 percent.

4.2.5. Lower Castaic Creek Watershed (HUC 180701020306)

The Lower Castaic Creek Watershed is located in the San Francisquito Unit of the ANF, and has a Summary Watershed Condition Category rating of III. This watershed drains approximately 30,296 acres; drainages in this watershed include those in Grasshopper Canyon, Marple Canyon, Violin Canyon, Bitter Canyon, Charlie Canyon, Tapia Canyon, Wayside Canyon, Hasley Canyon, and Romero Canyon, as well as Castaic Creek. FEMA has mapped 100-year floodplains associated with Castaic Creek below Castaic Dam, Hasley Canyon, Marple Canyon, Charlie Canyon, and several additional tributaries to Castaic Creek.

The NWI has mapped PFO wetlands in Tapia Canyon (T05N R16W Sections 21SW and 31NE), and PSS wetlands in Wayside Canyon (T04N R16W S32E). In Castaic Creek, the NWI has mapped PFO, PEM, and PSS wetlands along the banks of the creek in the vicinity of Castaic Junction. Additional PFO wetlands have been mapped in Sloan Canyon (T05N R17W Section 34NE).

In this watershed, Charlie Canyon, Bitter Canyon, and many of their tributaries have associated RCAs. In the ANF portion of the Lower Castaic Creek Watershed, there are approximately 13 RCAs.

Beneficial uses of surface waters in this watershed include Municipal and Domestic Supply, Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Hydropower Generation, Water Contact Recreation, Non-contact Water Recreation, Commercial and Sport Fishing, Warm Freshwater Habitat, Cold Freshwater Habitat, Wildlife Habitat, Rare, Threatened, or Endangered Species, and Spawning, Reproduction, and/or Early Development.

The southern portion of the Lower Castaic Creek Watershed lies above the Santa Clara River Valley East Groundwater Sub-basin.

BRRTP Alternative 1 would cross the ANF section of the Lower Castaic Creek Watershed from mile marker 71.5 to 80.3. Ground slope in the vicinity typically ranges from 20 percent to 30 percent, with slopes in some areas greater than 30 percent.

4.2.6. San Francisquito Canyon Watershed (HUC 180701020402)

The San Francisquito Canyon Watershed is located in the Elizabeth Unit of the ANF, and has a Summary Watershed Condition Category rating of I. This watershed drains an area of approximately 31,695 acres; drainages in this watershed include those in San Francisquito Canyon, South Portal Canyon, Dowd Canyon, Clearwater Canyon, Cherry Canyon, Bee Canyon, and Drinkwater Canyon. FEMA has mapped 100-year floodplains in San Francisquito Canyon, and in the lower reach of Bee Canyon.

The NWI has mapped a PFO wetland in San Francisquito Canyon in T05N R15W Section 6 and T05N R16W Section 1. San Francisquito Canyon creek is designated an R4 wetland. In the lower reach of San Francisquito Canyon creek, PEM wetlands have been mapped near the confluence with the Santa Clara River.

San Francisquito Canyon and many of its tributaries have associated RCAs. In the ANF portion of the San Francisquito Canyon Watershed, there are approximately 56 RCAs.

Beneficial uses of surface waters in this watershed include Municipal and Domestic Supply, Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Water Contact Recreation, Non-contact Water Recreation, Commercial and Sport

Fishing, Warm Freshwater Habitat, Wildlife Habitat, Rare, Threatened, or Endangered Species, Spawning, Reproduction, and/or Early Development, and Wetland Habitat.

The southern portion of the San Francisquito Canyon Watershed lies above the Santa Clara River Valley East Groundwater Sub-basin.

There is a Critical Biological Area within San Francisquito Canyon that is designated Critical Habitat for the California red-legged frog. In addition to the California red-legged frog, arroyo chub (*Gila orcutti*) and Santa Ana sucker (*Catostomus santaanae*) have been recorded in San Francisquito Canyon, immediately downstream of the PFO wetland. Unarmored threespine stickleback (*Gasterosteus aculeatus williamsoni*) was previously known to occupy San Francisquito Canyon, but is now believed to be extirpated following heavy flood events in 2005 (CDFG 2011).

BRRTP Alternative 1 would cross the ANF section of the San Francisquito Canyon Watershed from mile marker 81.4 to 81.7. Ground slope in this vicinity ranges from flat to slopes greater than 30 percent. BRRTP Alternatives 2 and 2a would cross this watershed from mile marker 46.4 to 55.8, most of which would be within the ANF. Ground slope in the vicinity of these Alternatives is generally between 20 percent and 30 percent, with areas of slopes greater than 30 percent. The Alternative 2a re-route (Green Valley Re-route) would also cross this watershed from mile marker 3.6 to 6.6; this stretch would be entirely within the ANF. Ground slope in the vicinity of this re-route are generally greater than 30 percent, with a few areas of lesser slope ranging from 10 percent to 20 percent.

4.2.7. Lower Bouquet Canyon Watershed (HUC 180701020202)

The Lower Bouquet Canyon Watershed is located in the Bouquet Unit of the ANF, and has a Summary Watershed Condition Category rating of III. This watershed drains an area of approximately 22,075 acres; drainages in this watershed include those in Haskell Canyon, Bouquet Canyon, Vasquez Canyon, Plum Canyon, Dry Canyon, and Pettinger Canyon. FEMA has mapped 100-year floodplains for Bouquet Canyon, Vasquez Canyon, Plum Canyon, Haskell Canyon, and Dry Canyon.

The NWI has mapped PFO wetlands in areas of Dry Canyon, Haskell Canyon, and Bouquet Canyon. In Bouquet Canyon, Vasquez Canyon, and Plum Canyon, the NWI has also mapped PSS wetlands (T05N R15W Section 34NE, T04N R15W Sections 6S and 9NW). The NWI has designated each of these drainages R4 wetlands.

Haskell Canyon, Pettinger Canyon, and many of their tributaries have associated RCAs. In the ANF portion of the Lower Bouquet Canyon Watershed, there are approximately 20 RCAs.

Beneficial uses of surface waters in this watershed include Municipal and Domestic Supply, Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Water Contact Recreation, Non-contact Water Recreation, Commercial and Sport Fishing, Warm Freshwater Habitat, Cold Freshwater Habitat, Wildlife Habitat, Rare, Threatened, or Endangered Species, Spawning, Reproduction, and/or Early Development, and Wetland Habitat.

Dry Canyon Creek is listed on the 2006 CWA Section 303(d) List of Water Quality Limited Segments Requiring TMDLs as impaired by high levels of fecal coliform.

The southern portion of the Lower Bouquet Canyon Watershed lies above the Santa Clara River Valley East Groundwater Sub-basin.

There are multiple known instances of unarmored threespine stickleback within Bouquet Creek south of the ANF boundary (CDFG 2011).

BRRTP Alternative 1 would cross the ANF section of the Lower Bouquet Canyon Watershed from mile marker 81.7 to 83.2. In the vicinity of this Alternative, ground slope is greater than 30 percent. This watershed would also be crossed by BRRTP Alternatives 2 and 2a from mile marker 55.9 to 60.7, all of which is located in the ANF. In the vicinity of these Alternatives, ground slope is typically between 20 percent and 30 percent, interspersed with areas of slopes less than 20 percent and slopes greater than 30 percent.

4.2.8. Elizabeth Lake Watershed (HUC 180701020301)

The Elizabeth Lake Watershed is located in the San Francisquito Unit of the ANF and has a Summary Watershed Condition Category rating of III. This watershed drains an area of approximately 11,411 acres; drainages in this watershed include those in Shake Canyon, Pine Canyon, Sterner Canyon, Forsythe Canyon, Spring Canyon, Abrams Canyon, Lucky Canyon, Munz Canyon, and Burns Canyon, all of which drain into Lake Hughes, Munz Lake, or Elizabeth Lake. FEMA 100-year floodplains have been mapped in Pine Canyon upstream from Lake Hughes, for Lake Hughes and Elizabeth Lake, and for the unnamed drainage east of Elizabeth Lake.

The NWI has mapped PFO and PEM wetlands from north of Lake Hughes (T07N R15W Section 22SE) to south of Elizabeth Lake, near Power Line Drive (T06N R14W Section 2NW). Near the eastern edge of Elizabeth Lake is a palustrine aquatic bed (PAB) wetland; in addition, Munz Lake has been designated a PAB wetland by the NWI. Hughes Lake and Lake Elizabeth have been designated L1UB wetlands. Lake Hughes, Munz Lake, and Elizabeth Lake are rift lakes, which are formed in depressions created where active or recent strike/slip fault movement has impounded drainage.

Pine Canyon and many of its tributaries have associated RCAs. In the ANF portion of the Elizabeth Lake Watershed, there are approximately 17 RCAs.

Beneficial uses of surface waters in this watershed include Municipal and Domestic Supply, Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Water Contact Recreation, Non-contact Water Recreation, Commercial and Sport Fishing, Warm Freshwater Habitat, Wildlife Habitat, and Rare, Threatened, or Endangered Species.

The Elizabeth Lake Watershed lies above the San Andreas Rift Zone portion of the Antelope Valley Groundwater Basin.

Elizabeth Lake is listed on the 2006 CWA Section 303(d) List of Water Quality Limited Segments Requiring TMDLs as impaired by eutrophication, organic enrichment/low dissolved oxygen, unhealthy levels of pH, and trash. Lake Hughes is listed as impaired by algae, eutrophication, fish kills, odor, and trash; Munz Lake is listed as impaired by eutrophication and trash.

BRRTP Alternatives 2 and 2a would cross the ANF section of the Elizabeth Lake Watershed from mile markers 46.0 to 46.4. Ground slope in the vicinity of these Alternatives ranges from 0 percent to 30 percent. The Alternative 2a re-route (Green Valley Re-route) would also cross the ANF section of this watershed from mile marker 0.7 to 3.0. Ground slope in the vicinity of this portion of Alternative 2a is generally greater than 30 percent, with areas of lesser slope ranging from 10 percent to 30 percent.

4.2.9. Elizabeth Lake Canyon Watershed (HUC 180701020304)

The Elizabeth Lake Canyon Watershed is located in the San Francisquito Unit of the ANF, and has a Summary Watershed Condition Category rating of III. This watershed drains an area of approximately 11,411 acres; drainages in this watershed include those in Elizabeth Lake Canyon, Kleine Canyon, Prospect Canyon, Turkey Canyon, Deer Canyon, Hiatt Canyon, Tule Canyon, South Tule Canyon, Ruby Canyon, Dry Gulch, and Warm Springs Canyon, as well as Fish Creek. FEMA has mapped 100-year floodplains in the northern portion of Elizabeth Lake Canyon and along the edges of the east branch of Castaic Lake.

The NWI has mapped a relatively large PFO wetland in the northern end of Elizabeth Lake Canyon (T07N R15W Section 27). Smaller PSS wetlands are mapped along the northeastern branch of Castaic Lake (T05N R16W Section 5NE), and small, isolated PFO wetlands are mapped along the west slopes of Elizabeth Lake Canyon at the 2,800-foot level and the 3,000-foot level, and north of Turkey Canyon between 3,400 feet and 4,000 feet. The NWI has designated Castaic Lake a L1UB wetland.

Elizabeth Lake Canyon and many of its tributaries have associated RCAs. In the ANF portion of the Elizabeth Lake Canyon Watershed, there are approximately 63 RCAs.

Beneficial uses of surface waters in this watershed include Municipal and Domestic Supply, Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Water Contact Recreation, Non-contact Water Recreation, Commercial and Sport Fishing, Warm Freshwater Habitat, and Wildlife Habitat.

The southern portion of the Elizabeth Lake Canyon Watershed lies above the Santa Clara River Valley East Groundwater Sub-basin.

The BRRTP Alternative 2a re-route (Green Valley Re-route) would cross the ANF section of the Elizabeth Lake Canyon Watershed from mile marker 3.0 to 3.6. Ground slope in the vicinity of this portion of the re-route are from 20 percent to greater than 30 percent.

4.2.10. Agua Dulce Canyon Watershed (HUC 180701020104)

The Agua Dulce Canyon Watershed is located in the Soledad (Aliso) Unit of the ANF, and has a Summary Watershed Condition Category rating of III. This watershed drains an area of approximately 18,814 acres; drainages in this watershed include those in Letteau Canyon, Willow Springs Canyon, Hauser Canyon, Agua Dulce Canyon, Santa Margarita Canyon, and Escondido Canyon. FEMA has mapped 100-year floodplains in the Sierra Pelona Valley from the confluence of the Agua Dulce, Hauser, and Letteau Canyon drainages south to Soledad Canyon.

The NWI has mapped small, isolated PFO wetlands in Letteau Canyon (T05N R13W Section 6), Escondido Canyon (T04N R14W Section 2NW, T05N R14W Sections 35NE and 36NE, and T05N R13W Section 30SW), and Agua Dulce Canyon (T04N R14W Section 3SE). PSS wetlands are mapped adjacent to the PFO wetlands in these canyons.

No RCAs have been identified in the ANF portion of the Agua Dulce Canyon Watershed.

Beneficial uses of surface waters in this watershed include Municipal and Domestic Supply, Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Water Contact Recreation, Non-contact Water Recreation, Commercial and Sport Fishing, Warm Freshwater Habitat, Wildlife Habitat, Rare, Threatened, or Endangered Species, and Wetland Habitat.

The Agua Dulce Canyon Watershed lies above the Acton Valley Groundwater Basin.

BRRTP Alternative 3 would cross through the ANF section of the Agua Dulce Canyon Watershed from mile marker 60.3 to 61.9. Ground slope in the vicinity of this Alternative typically ranges from 20 percent to 30 percent.

4.2.11. Mint Canyon Watershed (HUC 180701020106)

The Mint Canyon Watershed is located in the Soledad (Aliso) Unit of the ANF, and has a Summary Watershed Condition Category rating of III. This watershed drains an area of approximately 18,664 acres; drainages in this watershed include those in Mint Canyon, Spade Spring Canyon, Spade Canyon, Rowler Canyon, and Rush Canyon. FEMA has mapped 100-year floodplains for Mint Canyon, Spade Spring Canyon, and two tributaries (T04N R15W Section 2NE).

The NWI has mapped isolated PFO wetlands in Fryingpan Springs (T06N R13W Section 31SE). The drainages in Mint Canyon and Spade Spring Canyon are designated R4 wetlands.

Mint Canyon, Rowler Canyon, Spade Spring Canyon, and many of their tributaries have associated RCAs. In the ANF portion of the Mint Canyon Watershed, there are approximately 24 RCAs.

Beneficial uses of surfaces waters in this watershed include Municipal and Domestic Supply, Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Water Contact Recreation, Non-contact Water Recreation, Commercial and Sport Fishing, Warm Freshwater Habitat, and Wildlife Habitat.

Mint Canyon Creek is listed on the 2006 CWA Section 303(d) List of Water Quality Limited Segments Requiring TMDLs as impaired by high levels of nitrate and nitrite.

The northeast portion of the Mint Canyon Watershed lies above the Acton Valley Groundwater Basin and the southern portion of this watershed lies above the Santa Clara River Valley East Groundwater Sub-basin.

BRRTP Alternative 3 would cross through the ANF section of the Mint Canyon Watershed from mile marker 62.0 to 69.0. In the vicinity of this Alternative, ground slope is typically greater than 30 percent, with some areas with slopes between 20 percent and 30 percent.

4.2.12. Upper Bouquet Canyon Watershed (HUC 180701020201)

The Upper Bouquet Canyon Watershed is in the Bouquet Unit of the ANF, and has a Summary Watershed Condition Category rating of III. This watershed drains an area of approximately 24,517 acres; drainages in this watershed include those in Spunky Canyon, Bouquet Canyon, Martindale Canyon, Texas Canyon, Fall Canyon, Mystic Canyon, and Course Gold Canyon. Bouquet Reservoir is located in the northern portion of this watershed. FEMA has mapped 100-year floodplains for Bouquet Reservoir, and the lower reaches of Bouquet Canyon and Texas Canyon.

The NWI has mapped PSS and PFO wetlands in Bouquet Canyon just east of Bouquet Reservoir, and a PSS wetland on the western edge of the reservoir. The reservoir is designated an L1UB wetland. In Bouquet Canyon, near the confluence with the Texas Canyon drainage, the NWI has mapped PEM and PFO wetlands (T05N R15W Sections 21 and 28). The drainages in Bouquet Canyon, Texas Canyon, and several tributaries to bouquet Canyon are designated R4 wetlands.

Bouquet Canyon, Texas Canyon, and many of their tributaries have associated RCAs. In the ANF portion of the Upper Bouquet Canyon Watershed, there are approximately 46 RCAs.

Beneficial uses of surface waters in this watershed include Municipal and Domestic Supply Industrial Service Supply, Industrial Process Supply, Agricultural Supply, Ground Water Recharge, Freshwater Replenishment, Hydropower Generation, Water Contact Recreation, Non-contact Water Recreation, Commercial and Sport Fishing, Warm Freshwater Habitat, Cold Freshwater Habitat, Wildlife Habitat, Rare, Threatened, or Endangered Species, Spawning, Reproduction, and/or Early Development, and Wetland Habitat.

The southern portion of the Upper Bouquet Canyon Watershed lies above the Santa Clara River Valley East groundwater Sub-basin.

There are multiple known instances of unarmored threespine stickleback within Bouquet Creek south of Bouquet Reservoir to Texas Canyon (Hitchcock et al. 2006).

BRRTP Alternative 3 would cross through the ANF section of the Upper Bouquet Canyon Watershed from mile marker 69.1 to 70.1. In the vicinity of this Alternative, ground slope is typically greater than 30 percent.

5.0 GUIDING LAWS, REGULATIONS, POLICIES, AND DIRECTION

The proposed Project must comply with the following laws, regulations, and policies:

Angeles National Forest Land Management Plan. The United States Forest Service (USFS) developed a Land Management Plan (USFS 2005) for the Angeles National Forest (Forest), which provides management direction for activities within the Forest. The Plan includes a description of Program Strategies and Tactics geared toward achieving the desired goals of the Plan. Strategies associated with water resources include Watershed Function, Water Management, and Hazardous Materials.

Forest Service Handbook, Angeles National Forest. The Forest Service Soil and Water Conservation Practices Handbook (FSH 2509.22; USFS 2005) sets forth guidance for the delineation and management of Riparian Conservation Areas on the Angeles National Forest. This handbook is supplemental to the 2005 Angeles National Forest Land Management Plan.

Water Quality Management Best Management Practices. The USFS Pacific Southwest Region developed guidance for the practices, procedures, and Best Management Practices (BMPs) used for water quality management on USFS lands within the State of California. The BMPs described in this document are in conformance and compliance with the provisions and requirements of Sections 208 and 319 of the Clean Water Act (CWA), and are also within the guidelines of the Basin Plans developed by the nine California Regional Water Quality Control Boards.

Section 303(d) Clean Water Act. Section 303(d) unites the water quality management strategies of the CWA. Section 303(d) requires that states make a list of waters that exceed the minimum level of pollutants put in place by the CWA. For waters on this list, the states must develop total maximum daily loads (TMDLs), which account for all sources of the pollutants that caused the water to be listed. The TMDLs must account for contributions from both point sources and non-point sources, as defined by Section 402 of the CWA. In California, the State Water Resources Control Board (SWRCB) has interpreted state law to require that implementation of TMDLs be addressed when incorporated into Basin Plans (water quality control plans).

Section 401 Clean Water Act. Pursuant to Section 401 of the CWA, a water quality certification is required from the California Regional Water Quality Control Board (RWQCB) for Section 404 permit activities in individual Regions. The RWQCB certifies that the discharge complies with state water quality standards and ensures that there is no net loss of wetlands through impact avoidance, minimization, and mitigation. The ANF portion of the proposed Project is located in the jurisdiction of the Los Angeles RWCQB.

Section 404 Clean Water Act. Waters of the U.S. including wetlands are subject to U. S. Army Corps of Engineers (USACE) jurisdiction under Section 404 of the Clean Water Act CWA. A Section 404 permit is required for the discharge of dredged or fill material into Waters of the U.S. The Los Angeles District of the USACE would provide review and permitting services for this Project.

Wild and Scenic Rivers Act. The National Wild and Scenic Rivers System was created by Congress in 1968 (Public Law 90-542; 16 U.S.C. 1271 *et seq.*) to preserve certain rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The Act is notable for safeguarding the special character of these rivers, while also recognizing the potential for their appropriate use and development. Designated segments need not include the entire river, and may include tributaries.

Basin Plan. The California State Water Resources Control Board (SWRCB) requires individual RWQCBs to develop Basin Plans (water quality control plans) designed to preserve and enhance water quality and protect the beneficial uses of all Regional waters. Specifically, Basin Plans designate beneficial uses for surface waters and groundwater, set narrative and numerical objectives that must be attainted or maintained to protect the designated beneficial uses and conform to the States antidegradation policy, and describe implementation programs to protect all waters in the Regions. In addition, Basin Plans incorporate by reference all applicable State and Regional Board plans and policies, and other pertinent water quality policies and regulations. The ANF portion of the BRRTP is under the jurisdiction of the Basin Plan of the Los Angeles RWQCB.

Construction Storm Water Program. The SWRCB and the nine RWQCBs implement water quality regulations under the federal CWA and California Porter Cologne Water Quality Control Act. Existing water quality regulations require compliance with the National Pollutant Discharge Elimination System (NPDES) for discharges of storm water runoff associated with a construction activity.

Dischargers whose projects disturb one or more acres of soil are required to obtain coverage under the General Permit for Discharges of Storm Water Associated with Construction Activity (Construction General Permit, 2009-2009-DWQ). Construction activity subject to this permit includes clearing, grading, and disturbances to the ground such as stockpiling or excavation, but does not include regular maintenance activities performed to restore the original line, grade, or capacity of the facility.

The Construction General Permit requires the development and implementation of a Storm Water Pollution Prevention Plan (SWPPP). The SWPPP should contain a site map(s) which shows the construction site perimeter, existing and proposed buildings, lots, roadways, storm water collection and discharge points, general topography both before and after construction, and drainage patterns across the Project. The SWPPP must list Best Management Practices (BMPs) the discharger will use to protect storm water runoff and the placement of those BMPs. Additionally, the SWPPP must contain a visual monitoring program, a chemical monitoring program for "non-visible" pollutants to be implemented if there is a failure of BMPs, and a sediment monitoring plan if the site discharges directly to a water body listed on the 303(d) list for sediment.

A complete Notice of Intent Package, including SWPPP, and Notice of Termination must be uploaded to the SWRCB Storm Water Multiple Application and Report Tracking System (SMARTS) database by the Project Owner.

6.0 MANAGEMENT OBJECTIVES (DESIRED CONDITIONS)

Forest Goal 5.1 requires sustaining high water quality throughout Forest watersheds, streams, wetlands, and other water resources; Forest Goal 5.2 resolves to maintain and improve riparian conditions so that RCAs will contain primarily native botanical and wildlife species. Specifically, desired conditions within the BRRTP area includes improvement of habitat conditions for threatened, endangered, proposed, and candidate species (*e.g.*, arroyo toad and California red-legged frog), and reduction and control of exotic species. Achievement of these conditions requires management of water quality and water needs to provide for forest ecosystem needs and in-stream flows necessary to support surface and subsurface resources (USFS 2005).

7.0 IMPACT ASSESSMENT METHODOLOGY

Initial impact levels of each Alternative were evaluated by combining resource sensitivity and access level category (*i.e.*, level of impact expected from ground disturbance). All known water resources within the study corridors of each segment were inventoried and evaluated to determine potential impacts resulting from the Project.

Impacts to inventoried water resources were evaluated considering the following factors:
1. Construction, operation, and maintenance-related impacts;
2. Occurrence of affected water resources;
3. Water resource sensitivity levels;
4. Access level category (level of impact expected from ground disturbance);
5. BMPs or mitigation measures to reduce initial impact levels.

7.1 IMPACT MODEL

To determine the intensity of Project-related impacts, an impact model was developed for water resources. The impact assessment model combines resource sensitivity and access levels. The combination of these assessment variables determined the level of impact (high, moderate, low). The results of the impact assessment are presented in detail in Section 8.0 of this report.

Once initial impacts levels were established for each segment, BMPs or specific measures for mitigating or reducing predicted high- or moderate-level impacts were applied. Residual impacts are the impacts remaining after application of these measures.

7.1.1. RUSLE Analysis

Initial analysis of Project-related impacts revealed the potential for impacts to water quality through erosion of disturbed soils, leading to increased sedimentation and turbidity of receiving waters within the Angeles National Forest. At the request of the USFS, POWER Engineers, Inc. prepared a watershed analysis to predict erosion rates (tons/acre/year) that would potentially result from construction of the alternative transmission line routes in the Angeles National Forest. This analysis allows for the comparison of potential impacts on sensitive aquatic habitat and species, and beneficial uses of waters from construction of the alternative routes within the Angeles National Forest. The RUSLE Analysis is included in Appendix A of this report.

7.1.2. Hydrologic Modeling

To determine what effect, if any, Project-related ground disturbance would have on watersheds within the Forest, a range of subwatersheds were modeled using the hydrologic modeling program WinTR-55. Due to the comparatively large size of the 6th level watersheds, a relative approach was utilized to determine effects of BRRTP Alternatives on watershed hydrology. Rather than delineating and modeling all 6th level watersheds in the BRRTP area, a representative sample of smaller subwatersheds was selected, in collaboration with Mr. Gregory, to provide a representative sample of the varied characteristic of the area watersheds. If little or no change were determined in these subwatersheds, then it could be logically assumed that similar percentages of change (*i.e.*, post-construction changes from baseline) would occur in similar subwatersheds with similar Project-related impacts. If, however, the model produced significant differences between pre- and post-construction conditions, modeling of the remaining subwatersheds would be required to quantify impacts.

Of the 12 watersheds that would be affected by BRRTP Alternatives, five sample subwatersheds were selected with acreages that fell within the limitations of the WinTR-55 program. Each of the sample subwatersheds are situated in different locales, are of varying sizes, and each BRRTP Alternative is represented (for maps of sample subwatersheds, please refer to Appendix B, Studied Watersheds).

Model Input

A brief summary of model inputs are outlined below. For a more detailed description of the model inputs and any associated assumptions, please refer to Appendix C.

- Storm Data
    - 24-Hour Design Storm Data obtained from NOAA Precipitation Frequency Data Server website at http://hdsc.nws.noaa.gov/hdsc/pfds/pfds_map_cont.html?bkmrk=ca
- Time of Concentration
    - Delineated using GIS for each subwatershed
    - Assumed 100 feet of sheet and shallow concentrated flow, followed by channel flow
- Land Use
    - Utilized National Land Use Cover Datasets (NLCD) in GIS format and cover type was converted as described in the Assumptions Table to fit WinTR-55 input requirements
    - For post-construction conditions, pre-construction conditions were modified by "burning in" access roads. This was the only variable modified to reflect pre- and post-construction conditions.
    - Access roads were conservatively assumed to be impervious, and 10 meters (32.8 feet) wide (typical dirt and gravel access roads are pervious and less than 5 meters wide).

7.2 RESOURCE SENSITIVITY

Resource sensitivity is the measure of the probable adverse effect that a resource would experience through direct or indirect impacts associated with construction, operation, and maintenance of the Project. Adverse effects to water resources were assessed using three major criteria: the susceptibility of the resource to the potential changes resulting from construction, operation, and maintenance activities; significance of the potential change on the resource; and occurrence or abundance of affected water resources within the study area. Also considered were hydrological capacity, accessory benefits (e.g., plant and wildlife habitat), and potential to affect engineering and design.

Determination of Potential Change. Changes are brought about by construction of the Project, the physical presence and operation of the Project facilities, and management and maintenance of the Project facilities. This potential for change is predicted by evaluating environmental conditions, the Project description, and implementation specifications.

Significance of Changes. The effect of potential changes on resources is described in levels of significance. The significance of any change relates to the immediate- and long-term effects that the change may have, either directly or indirectly, on the resource. Accordingly, a sensitivity value of maximum, moderate, or minimal was assigned to each resource to represent the potential level of significance.

7.2.1. Sensitivity Values

Sensitivity values are based on the function and value of the resource, and the level of impacts or adverse effect to that resource. For example, Palustrine Forested (PFO) wetlands are designated at a maximum sensitivity level because they provide high functional values and would be permanently impacted by clearing, ROW maintenance, and filling for access road construction.

A **maximum** sensitivity value was assigned to:

- Areas with occurrences of perennial rivers or streams, including Lower Perennial Riverine (R2) wetlands;
- Palustrine Emergent (PEM), Palustrine Scrub-Shrub (PSS), or PFO wetlands;
- Riparian Conservation Areas.

A **moderate** sensitivity value was assigned to:

- 100-year floodplains;

- Intermittent rivers and streams, including Intermittent Riverine (R4) wetlands;
- Partially hydric soils.

A **minimal** sensitivity value was assigned to:

- Palustrine Unconsolidated Bottom (PUB) wetlands;
- Aqueducts;
- Wells and groundwater.

Lands not associated with a water resource feature or indicator were not considered sensitive.

7.2.2. Access Levels and Ground Disturbance

The criteria for assessing the initial ground disturbance impacts to water resources are summarized in Table 3. Access level categories and resource sensitivity levels were the main factors used in estimating potential impact levels.

TABLE 3. WATER RESOURCES IMPACTS BY ACCESS LEVEL CATEGORY

Resource		Access Level Categories						
		1	2	3	4	5	6	H
Perennial river or stream		Low	Low	Moderate	High	High	High	High
Intermittent river or stream		Low	Low	Moderate	Moderate	High	High	High
Aqueduct		Low	Low	Moderate	High	High	High	High
Wells		Low	Low	Low	Low	Low	Low	Low
Riparian habitat and RCAs		Low	Moderate	High	High	High	High	High
SEAs		Low	Low	Moderate	Moderate	High	High	High
NWI wetland	PEM	Low	Moderate	High	High	High	High	High
	PFO	Low	Moderate	High	High	High	High	High
	PUB	Low	Low	Moderate	Moderate	High	High	High
	R2	Low	Low	Moderate	High	High	High	High
	R4	Low	Low	Moderate	Moderate	High	High	High
Partially hydric soils		Low	Low	Moderate	Moderate	High	High	Moderate
100-year floodplain		Low	Low	Moderate	Moderate	High	High	Moderate

7.3 IMPACT LEVELS

Water resource impact determinations are based on significance criteria derived from CEQA Guidelines (Appendix G, Environmental Checklist Form, Section IX). Impacts are considered significant if the Project:

- Violates any water quality standards or waste discharge requirements, creates new sources of polluted runoff, or otherwise substantially degrades water quality.
- Substantially depletes groundwater supplies or interferes substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted).
- Substantially alters the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site.

- Substantially alters the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increases the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.
- Creates or contributes runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provides substantial additional sources of polluted runoff.
- Has a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means.
- Places housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map.
- Places within a 100-year flood hazard area structures which would impede or redirect flood flows.
- Exposes people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam.
- Results in or is subject to damage from inundation by seiche, tsunami, or mudflow.

7.4 IMPACT ASSESSMENT METHODOLOGY BY PROJECT COMPONENT

All components of the proposed BRRTP are described in this section; however, for the purposes of this report, only potential impacts related to those components that would cross through the ANF, or that would affect watersheds within the ANF, will be discussed hereafter. For details regarding impact assessment for those components and sections of the BRRTP that would be located outside the ANF, please refer to the Water Resources Technical Report.

7.4.1. 230 kV Transmission Line

To assess impacts to water resources associated with the new 230 kV transmission line, each water resource within 0.5 mile of the proposed centerline was mapped at a scale of 1:24,000 using GIS. Based on this map, location-specific analyses of temporary and permanent impacts could be made, and after considering the inherent sensitivity of perennial streams, intermittent streams, NWI wetlands, and other water resources that could be affected, a determination was made of whether high, moderate, or low impacts would result. This analysis was conducted throughout all Project Alternatives.

For each of the initially proposed segments, the presence of streams, wetlands, aqueducts, wells, riparian habitat, RCAs, hydric soils, and 100-year floodplains within one-half mile of the centerline was determined to the nearest tenth of a mile, and mile marker begin/end points were recorded. Permanent and temporary impacts to each resource (in acres) were determined based on the ground disturbance level applicable to the location evaluated. Permanent disturbance within the ground disturbance areas would be limited to the tower foundations and the footprint of new access roads. All other ground disturbance would be temporary.

All initial probable 230 kV component impacts were re-assessed in light of the effectiveness of USFS BMPs, BRRTP General Practices (GPs) and Mitigation Measures (MMs) to reduce potential impacts. As summarized in Table 3 above, the initial 230 kV Project impacts were assessed with consideration to the sensitivity of each water resource type. After assigning initial ground disturbance impact levels for all water resources traversed by the 0.5-mile corridor for the centerline, BMPs, GPs and MMs were considered and the degree to which they would reduce the initial impact was evaluated. These BMPs, GPs and MMs were then applied, as appropriate, to reduce the level of residual impacts to each water resource.

7.4.2. New 230 kV Circuit

In the Castaic Transmission Corridor, LADWP has two existing parallel double-circuit 230 kV towers. The northern towers hold the Castaic-Olive 230 kV Transmission Line and the second position is vacant.

LADWP proposes the addition of approximately 12 miles of a new 230 kV transmission circuit onto existing Castaic – Olive 230 kV Transmission Line structures (towers 1-1 through 12-1).

7.4.3. Reconductoring

As part of the BRRTP, LADWP is proposing to upgrade the existing BR-RIN line from the Barren Ridge Switching Station to the Rinaldi Substation with larger-capacity conductors. Permanent impacts would occur from rehabilitation of the existing access and spur roads, and clearing of the right-of-way (ROW). By utilizing the existing structures and ROW, the Project would minimize permanent impacts while allowing additional transmission capacity along the corridor. Temporary impacts would occur where equipment staging, line work, or construction traffic access would be needed. Upgrading the existing BR-RIN would involve approximately 13 miles of USFS lands and four miles of BLM lands.

7.4.4. New Haskell Canyon Switching Station

Ground disturbance at the Haskell Canyon Switching Station site would lead to permanent impacts within the proposed switching site fence line and associated new access roads. The station would require an area of approximately 400 feet by 600 feet to accommodate the necessary equipment such as steel support structures, circuit breakers, disconnect switches, and associated equipment, and a relay house and control house containing control and protective relaying equipment. Temporary impacts within the area would occur where equipment staging, line work, or construction traffic access would be needed.

7.4.5. Expansion of Barren Ridge Switching Station

Expansion of the Barren Ridge Switching Station site would lead to permanent impacts within the proposed site fence line. LADWP proposes expansion of the existing Barren Ridge Switching Station to the east side by 235 feet by 500 feet for a total station size of 485 feet by 500 feet (approximately 5.6 acres). Existing access roads would be used and permanent impacts would be restricted to the site expansion. Temporary impacts within the area would occur where equipment staging, line work, or construction access would be needed.

7.5 IMPACTS AND MITIGATION PLANNING

Potential impacts to water resources include temporary (construction-related) impacts and long-term (permanent) impacts. When evaluating potential impacts to water resources, it was assumed that the Project would comply with all applicable federal, state, and local regulatory requirements that protect surface water and groundwater.

The USFS, Pacific Southwest Region has established water quality protection BMPs and BMP evaluation protocols for use on Forest lands. The following USFS BMPs will be implemented on Forest lands as part of the proposed Project:

PRACTICE 2-1: Locate and design roads with minimal resource damage. Roads will be located to fit the terrain, and to minimize damage to improvements and resources. Sensitive areas such as wetlands, inner gorges, and unstable ground will be avoided to the extent practical.

PRACTICE 2-2: Erosion Plan. An erosion plan will be included as part of the required SWPPP, and implemented throughout the Project to limit and mitigate erosion and sedimentation during construction activities.

PRACTICE 2-3: Timing of construction activities. To minimize erosion and sedimentation, construction activities will be planned to occur during minimal runoff periods to the extent practical.

PRACTICE 2-4: Stabilization of slope surfaces and spoil disposal areas. To minimize post-construction erosion from exposed or disturbed work areas, LADWP shall prepare a Restoration and Revegetation

Plan for the project. The Plan shall be incorporated into the Special Use Authorization to be issued by the USFS.

PRACTICE 2-12: Servicing and refueling of equipment. To prevent pollutants such as fuels, lubricants, and other harmful materials from being discharged into or near rivers, streams, or wetlands, refueling, or addition or changing of oil and other fluids for equipment and heavy machinery shall be performed only at approved staging and construction areas. Staging and construction yards will be located on upland sites and spill containment measures will be used to minimize risk of spill or drainage into waterways. Oil and other fluids will be disposed of as required by California law. Emergency refueling, or emergency addition or changing of oil or other fluids shall not be performed within 500 feet of natural stream channels or wetlands.

PRACTICE 7-2: Floodplain hazard analysis and evaluation. Structures and new access roads placed with a 100-year floodplain will be engineered so that they do not impede or redirect flood flows or raise the flood elevation; in addition, structures located within the 100-year floodplain of rivers and streams will be designed to minimize the capture of flood debris to prevent flow obstructions and scouring during flood flows.

PRACTICE 7-3: Protection of wetlands. To avoid adverse water quality impacts associated with destruction, disturbance, or modification of wetlands, Project features will be places so as to avoid sensitive features including, but not limited to, riparian areas and water courses. If sensitive water resource features such as riparian areas, habitats of endangered species, streambeds, and wetlands cannot be avoided, a qualified biological contractor shall conduct site-specific assessments for each affected site. These assessments shall be conducted in accordance with USACE wetland delineation guidelines, as well as California Department of Fish and Game streambed and lake assessment guidelines, and shall include impact minimization measures to reduce wetland impacts. Staging/storage areas for equipment and materials shall be located outside of riparian areas. Construction of new access through streambeds that require filling for access purposes would require a Streambed Alteration Agreement from CDFG and/or consultation with the USACE.

PRACTICE 7-4: Forest and Hazardous Substance Spill Prevention, Countermeasure, and Control (SPCC) Plan. To prevent contamination of waters from accidental spills, LADWP will prepare or update an existing Spill Prevention, Countermeasure, and Control Plan for proposed and/or expanded switching stations if necessary or required by EPA guidelines. The plans will include engineered and operational methods for preventing, containing, and controlling potential fluid releases, and provisions for quick and safe cleanup.

PRACTICE 7-5: Control of activities under Special Use Permit. To protect surface and subsurface water quality from physical, chemical, and biological pollutants resulting from activities that are under Special Use Permit, the Project will comply with conditions of the Permit, including management requirements and mitigation measures necessary to protect water quality. The Project will also conform to all applicable State and local regulations governing water quality and sanitation.

PRACTICE 7-6: Water quality monitoring. A water quality monitoring plan will be prepared as part of the required SWPPP. Analysis of the data will be performed by a State-certified laboratory, trained Forest personnel, or combinations of these as appropriate.

PRACTICE 7-7: Management by closure to use (seasonal, temporary, and permanent). If the condition of a watershed becomes sensitive to the extent that any use during a given portion of year could result in soil and/or land stability problems and associated adverse effects could adversely affect water quality, the Forest Supervisor, District Ranger, or Forest Service Officer responsible for resource protection may determine that a particular resource needs protection from use and decide to close an area. This would occur only after an evaluation of alternative methods of protection dictate that closure is the required action, and is usually a last step protective measure.

In addition to the USFS BMPs, the GPs described in Table 4 below are measures that would be included in the Project description and implemented as part of the proposed Project.

Impact analysis assumed that all BMPs and GPs would be implemented as defined. The specifically recommended Mitigation Measures described in Table 5 below would be used on a site-specific basis to minimize Project-related impacts if it is determined that BMPs and GPs would not fully mitigate the impacts for which they are presented.

TABLE 4. GENERAL PRACTICES

	Plans
GP-1	**Plan of Development & Construction, Operation and Maintenance Plans.** In consultation with the Forest Service and BLM Authorizing Officers prior to construction, LADWP shall develop a Construction, Operation and Maintenance Plan (COM Plan) with the Forest Service and Plan of Development (POD) with BLM. These plans shall be attached to and become a part of the Special Use and Right-of-Way Authorizations. The COM Plan and POD shall include, at a minimum, road maintenance specifications, vegetation treatment and rehabilitation specifications, and conditions on maintenance and replacement of improvements. The agencies may combine the POD and COM plans into a single document for the Project.
GP-3	**Hazardous Materials/Waste Management Plan.** A project-specific hazardous materials management and hazardous waste management program will be developed prior to initiation of the project. The program will outline proper hazardous materials use, storage and disposal requirements as well as hazardous waste management procedures. The program will identify types of hazardous materials to be used during the project and the types of wastes that will be generated. All project personnel will be provided with project-specific training. This program will be developed to ensure that all hazardous materials and wastes were handled in a safe and environmentally sound manner. Hazardous wastes will be handled and disposed of according to applicable rules and regulations. Employees handling wastes will receive hazardous materials training and shall be trained in hazardous waste procedures, spill contingencies, waste minimization procedures and Treatment, Storage and Disposal Facility (TSDF) training in accordance with OSHA Hazard Communication Standard and 22 CCR. If degraded soil or groundwater is encountered during excavation (e.g., there is an obvious sheen, odor, or unnatural color to the soil or groundwater), it shall be excavated, tested, and disposed of in accordance with state hazardous waste disposal requirements. The Plan shall also include procedures detailing emergency responses to releases of hazardous materials. It will prescribe hazardous materials handling procedures for reducing the potential for a spill during construction, and will include an emergency response program to ensure quick and safe cleanup of accidental spills. All hazardous materials spills or threatened release, including petroleum products such as gasoline, diesel, and hydraulic fluid, regardless of the quantity spilled, will be immediately reported to the appropriate agency as outlined in the Plan if the spill has entered a navigable water, stream, lake, wetland, or storm drain, if the spill impacted any sensitive area including conservation areas and wildlife preserves, or if the spill caused injury to a person or threatens injury to public health. All construction personnel, including environmental monitors, will be aware of state and federal emergency response reporting guidelines.
GP-5	**Stormwater Pollution Prevention Plan.** A project-specific Construction Stormwater Pollution Prevention Plan (SWPPP) will be prepared and implemented prior to the start of construction. The SWPPP will utilize Best Management Practices (BMPs) to address the storage and handling of hazardous materials and sediment runoff during construction activities.
GP-6	**Spill Prevention, Countermeasure, and Control Plan.** LADWP will prepare or update existing Spill Prevention, Countermeasure, and Control Plan (SPCC Plan) for proposed and/or expanded switching stations if necessary or required by EPA guidelines. The plans will include engineered and operational methods for preventing, containing, and controlling potential fluid releases, and provisions for quick and safe cleanup.
GP-7	**Soil Management Plan.** A Soil Management Plan will be developed and implemented for construction of the proposed Project. The objective of the Soil Management Plan is to provide guidance for the proper handling, onsite management, and disposal of impacted soil that might be encountered during construction activities. The plan will include practices that are consistent with California Title 8, Occupational Safety and Health Administration (Cal-OSHA) regulations, as well as appropriate remediation standards that are

	protective of the planned use. The Plan will provide guidelines for identification of impacted soil, assessing impacted soil, soil excavation, impacted soil storage, verification sampling, and impacted soil characterization and disposal. In the event that potentially contaminated soils are encountered within the footprint of construction, soils will be tested and stockpiled. The appropriate Certified Unified Program Agency (CUPA) will determine whether further assessment is warranted.
Design	
GP-11	Project features will be placed so as to avoid sensitive features including, but not limited to, riparian areas, water courses, and cultural sites, and/or to allow conductors to clearly span the features, within limits of standard tower design. This will minimize the amount of sensitive features disturbed and/or reduce visual contrast.
GP-12	Drainage control features will be installed, as appropriate, to minimize the amount of stormwater flow from areas of active construction. Details would be described in the SWPPP.
Construction Vehicles/Equipment	
GP-15	All trucks hauling soils or other loose materials shall be covered, or maintain at least two feet of freeboard (distance between the material and the top of the truck).
GP-16	Where visible soil material is carried onto adjacent public streets, the affected streets shall be cleaned daily with water sweepers.
GP-17	All vehicles and equipment operating within 100 feet of an active stream will be inspected daily to ensure they are free of any leaks of fuel, cooling, or lubricating fluids.
GP-18	All construction vehicles shall maintain a hazardous materials spill kit, which shall include absorbent materials, tarps, small storage containers or waterproof bags, and latex gloves. Field personnel shall be made aware of these kits and instructed on how to use them.
GP-19	Refueling, or addition or changing of oil and other fluids for equipment and heavy machinery shall be performed only at approved staging and construction yards. Staging and construction yards will be located on upland sites and spill containment measures will be used to minimize risk of spill or drainage into waterways. Oil and other fluids will be disposed of as required by California law. Emergency refueling, or emergency addition or changing of oil or other fluids shall not be performed within 500 feet of natural stream channels or wetlands.
GP-20	Helicopters utilized for construction will be refueled at helicopter staging areas or local airports. Procedures will include the use of drop cloths made of plastic and drip pans and trays to be placed under refilling areas to ensure that chemicals do not come into contact with the ground. Refueling areas will be located in designated areas where absorbent pads and trays are available.
Access Roads	
GP-23	The alignment of any new access roads or overland routes shall follow the designated area's landform contours where possible, providing that such alignment does not additionally impact resource values.
GP-24	To the extent practical, any re-grading of access roads shall be the minimum necessary to provide safe access of construction equipment, and erosion control measures.
GP-25	Construction vehicles shall use paved roads to access the construction site when available.
GP-33	In areas where soils and vegetation are particularly sensitive to disturbance, existing access roads would be repaired only in areas where they are otherwise impassable or unsafe.
Construction Areas	
GP-34	Construction activities shall be limited to the designated right-of-way and approved access and work areas as identified in the ROD and POD. Any deviations from the approved areas must be cleared with the jurisdictional agency and/or landowner.
GP-35	Grading areas shall be clearly marked and no equipment or vehicles shall disturb slopes or drainages outside of the grading area.
GP-36	No paint or permanent discoloring agents will be applied to rocks or vegetation to indicate survey or construction activity limits.
GP-37	In construction areas (e.g., marshalling yards, tower sites, spur roads from existing access roads) where ground disturbance is significant or where recontouring is required, surface restoration shall occur as required by the landowner or land management agency. The method of restoration will normally consist of returning disturbed areas back to their natural contour, reseeding, installing cross drains for erosion control as necessary, placing water bars in the road as necessary, and filling ditches.
GP-38	Soil excavated from construction activities shall not be left at work areas where the slopes exceed 10 percent or where the work area is within 100 feet of a natural stream or waterbody (receiving water). In these situations, loose soil shall be used elsewhere within the immediate area or stockpiled at the staging area. Stockpiled soil shall be managed as required by the SWPPP. No stockpiling or spreading of soil or

	other materials shall occur within stream channels.
GP-39	During grading or excavation work for the Project, the contractor shall observe the exposed soil for visual evidence of contamination. If visual contamination indicators are observed during construction, the contractor shall stop work until the material is properly characterized and appropriate measures are taken to protect human health and the environment. The contractor shall document the exact location of the contamination and shall immediately notify a designated Environmental Monitor and propose actions for addressing the contamination in accordance with the Soil Management Plan.
GP-40	Existing watering facilities (e.g., tanks, developed springs, water lines, wells, etc.) will be repaired or replaced, if they are damaged or destroyed by construction activities, to their pre-disturbed condition as required by the landowner or land management agency.
GP-41	Allow natural vegetation to reoccur on temporarily disturbed areas following the completion of construction.
GP-43	Every effort will be made to minimize vegetation removal and permanent loss at construction sites. Native vegetation will be flagged for protection or stockpiled for recontouring use at the discretion of the Biological Monitor and the Construction Supervisor.
GP-44	In construction areas where recontouring is not required, vegetation will be left in place wherever possible and the original contour will be maintained to avoid excessive root damage and allow for resprouting. Disturbance will be limited to overland driving where feasible to minimize changes in the original contours.
GP-45	Use of heavy equipment within a flowing channel will be avoided if possible; however, should it be necessary, the Environmental Monitor will be notified prior to initiation of construction activities to allow adequate time for site visits and surveys, if necessary.
GP-46	Asphalt or cement equipment will not be rinsed in, nor excess products deposited into any stream or other waterway. Asphalt or concrete effluent will not be allowed to enter into stream or RCA. Effluent will be removed from standing water and prevented from entering a waterway.
GP-47	Fill material, including brush, loose soils, and other similar debris will not be deposited within a stream channel or on a stream bank.
Surveys/Monitoring	
GP-48	**Biological Monitor.** For areas identified as environmentally sensitive, such as streams, wetlands, riparian areas, and other environmentally sensitive areas, a biological monitor shall be present during ground disturbing construction activities. The qualified biologist shall conduct monitoring for any area subject to disturbance from construction activities that may impact biological resources. The biological monitor's duties include minimizing impacts to special-status species, native vegetation, wildlife habitat, and unique resources, as well as to identify potential issues or impacts to biological resources and report those to the authorized biologist. Where appropriate, the monitor will flag the boundaries of biologically sensitive areas and monitor any construction activities in these areas to ensure that ground disturbance activities and impacts occur within designated limits.
GP-49	**Worker Environmental Awareness Program.** A Worker Environmental Awareness Program (WEAP) will be implemented to educate all construction personnel of the area's environmental conditions and the environmental protection measures that must be adhered to. An environmental training program will be established to communicate environmental concerns and appropriate work practices, including spill prevention, emergency response measures, protection of biological and cultural resources, and proper Best Management Practice (BMP) implementation, to all construction and maintenance personnel.
Coordination/Permits	
GP-50	Prior to construction, LADWP shall consult with all federal, state, and local agencies, including local agency consortiums, having jurisdiction over lands affected by the proposed Project's ROW and ancillary facilities to ensure that no permanent restrictions or preclusions of their land management practices occur.
GP-53	Incorporate riparian area avoidance and permit measures. The following actions and all permit conditions detailed within the Nationwide 12 permit and RWQCB 401 water quality certification (subject to separate approval) would be implemented by the construction manager and environmental compliance monitor(s). Before construction, qualified resource specialists would stake and flag or fence exclusion zones around all identified riparian woodlands. Such exclusion zones would include a 10-foot buffer to preclude sediment intrusion into the riparian areas. Earth-moving activities would be restricted from these zones, although essential vehicle operation and foot travel would be permitted on existing roads, bridges, and crossings. All other construction activities, vehicle operation, material and equipment storage, and other surface-disturbing activities would be prohibited within the exclusion zone. In areas where riparian habitats are unavoidable, the construction manager in consultation with the lead environmental compliance inspector would narrow the width of the centerline to the maximum extent allowable. New spur roads and existing access road improvements would be constructed and implemented using methodology that preserves existing hydrology. Tower pad clearance would be minimized to the maximum extent allowable. All

	temporarily disturbed riparian areas that would not be utilized for future routine operation and maintenance activities would be restored to ensure no net loss of habitat functions and values. Following construction activities, the areas would be restored as soon as practicable.
GP-54	Construction crews will avoid impacting the streambeds and banks of any streams along the route to the extent feasible. When construction or maintenance work affects the bed, bank or margins of a stream under CDFG jurisdiction, LADWP will notify CDFG as required under Fish and Game Code Section 1602, which may include securing a Streambed Alteration Agreement.

TABLE 5. SPECIFICALLY RECOMMENDED MITIGATION MEASURES

Measure	Description
HYD – 1	For Project construction and operation, off-road or cross-country access routes shall be preferred, as feasible, over the construction of new access roads. Such access roads will be approved in advance by the Environmental Monitor and the Project Manager and be flagged with easily seen markers. Any new access roads shall be constructed by crushing, rather than blading, wherever possible. Existing crossings shall be utilized at perennial streams, wetlands, and irrigation channels to the extent feasible. New access roads not required for ongoing maintenance shall be permanently closed after construction using the most effective and least environmentally damaging methods appropriate to that specific area, with concurrence of the landowner or land manager (e.g., stockpiling and replacing topsoil, or rock replacement).
HYD – 2	Roads would be built as near as possible to right angles to the streams and washes. Culverts would be installed where necessary. All construction and maintenance activities shall be conducted in a manner that would minimize disturbance to vegetation, drainage channels, and intermittent or perennial stream banks. In addition, road construction would include dust-control measures during construction in sensitive areas. All existing roads would be left in a condition equal to or better than their condition prior to the construction of the transmission line.
HYD – 3	New impervious areas associated with temporary construction will be restored to existing conditions, including but not limited to revegetation, to the extent possible after completion of Project construction.
HYD – 4	Stormwater drainage inside switching station walls will be designed to minimize erosion and increase sediment control. Internal runoff would be released from the switching station by means of surface drainage structures designed to filter contaminants from water flow. Drainage from the property would be collected and controlled by surface improvements, as detailed in the SWPPP.
HYD – 5	Structures and new access roads placed within a 100-year floodplain will be engineered so that they do not impede or redirect flood flows or raise the flood elevation.
HYD – 6	Structures located within the 100-year floodplain of rivers and streams will be designed to minimize the capture of flood debris to prevent flow obstructions and scouring during flood flows.
HYD – 7	Structures located adjacent to or downslope of lakes and reservoirs will be designed to minimize damage from inundation of a seismic seiche.
HELICOPTER	Helicopter Mitigation shall be implemented in steep areas of the Angeles National Forest where access is limited. During final design of the Project, areas other than those currently identified on Alternatives 1 and 2a may potentially require helicopter construction of the towers. This determination would generally be made where tower sites have no existing access roads within 300 feet and slopes are greater than 25 percent. Final identification of these tower sites would be determined and agreed upon by USFS, BLM and LADWP.
AIR – 2a	**Implement Construction Fugitive Dust Control Plan.** The construction contractor shall develop a Fugitive Dust Emission Control Plan for construction work. Measures to be incorporated into the plan include, but are not limited to, the following where practical: • Water the disturbed areas of the active construction sites in sufficient quantities to prevent the generation of visible dust plumes. Watering may not be required in wet weather. Soil binders may be used in lieu of watering where soil binders are appropriate and prevent the generation of visible dust plumes. • Enclose, cover, or apply water a minimum of twice daily to exposed piles with a five percent or greater silt content. • ARB-certified and agency-approved (on federal lands) non-toxic soil binders shall be applied per manufacturer recommendations to active unpaved roadways, unpaved staging areas, and unpaved parking area(s) throughout construction (as allowed by responsible agencies such as the USFS and BLM) to reduce fugitive dust emissions. Other watering products, selected from lists available from the Environmental Protection Agency's (EPA's) Environmental Technology Verification program or the SCAQMD, may be applied per manufacturer recommendations in place of the ARB-certified soil binders if such products can be reasonably demonstrated to be as effective as the ARB-certified non-

Measure	Description
	toxic soil binders and be approved by the affected federal agency. • Water all roads used for any vehicular traffic at least once per every two hours of active operations [3 times per normal 8-hour work day]; OR Water all roads used for any vehicular traffic once daily and restrict vehicle speeds to 15 miles per hour. Apply a chemical stabilizer to all unpaved road surfaces in sufficient quantity and frequency to maintain a stabilized surface, to reduce fugitive dust emissions. • All vehicle tires shall be inspected, are to be free of dirt, and washed as necessary prior to entering paved roadways. In lieu of washing vehicle tires, the construction contractor may sweep roads on a regular basis or employ similar methods to reduce dust track-out. • Install wheel washers or wash the wheels of trucks and other heavy equipment where vehicles exit unpaved areas. • Cover all trucks hauling soil and other loose material, or require at least two feet of freeboard. • Establish a vegetative ground cover (in compliance with biological resources impact mitigation measures) as appropriate or otherwise create stabilized surfaces on all unpaved areas at each of the construction sites after active construction operations have ceased. • Increase the frequency of watering unpaved surfaces under active construction to more than three times daily, or implement other additional fugitive dust mitigation measures, to all active disturbed fugitive dust emission sources as required by SCAQMD Rule 403 prior to wind events. • Travel routes to each construction site shall be developed to minimize unpaved road travel.
AIR – 2b	**Properly Maintain Mechanical Equipment.** The construction contractor shall ensure that all mechanical equipment associated with Project construction is properly tuned and maintained in accordance with the manufacturer's specifications to the extent feasible.
AIR – 2f	**Off-road Diesel-fueled Equipment Standards.** All off-road construction diesel engines not registered under ARB's Statewide Portable Equipment Registration Program, which have a rating of 50 horsepower (hp) or more, shall meet, at a minimum, the Tier 2 California Emission Standards for Off-Road Compression-Ignition Engines as specified in California Code of Regulations, Title 13, Section 2423(b)(1) unless such engine is not available for a particular item of equipment. In the event a Tier 2 engine is not available for any off-road engine larger than 100 hp, that engine shall be equipped with a Tier 1 engine. In the event a Tier 1 engine is not available for any off-road engine larger than 100 hp, that engine shall be equipped with a catalyzed diesel particulate filter (soot filter), unless certified by engine manufacturers that the use of such devices is not practical for specific engine types. Equipment properly registered under and in compliance with ARB's Statewide Portable Equipment Registration Program are in compliance with this mitigation measure.
BIO – 1	*Provide restoration/compensation for impacted sensitive vegetation communities.* **1a.** The intent of this mitigation measure is to require LADWP to restore disturbed sites to pre-construction conditions or the desired future conditions per the Angeles National Forest (ANF) Land Management Plan (LMP). Prior to construction LADWP shall have a qualified biologist, where concurrence on the biologist has been provided by the USFS and BLM, document the community type and acreage of vegetation that would be subject to Project disturbance. Impacts to all oaks and native trees will be documented by identifying the species, number, location, and diameter at breast height (DBH). On non-federal lands, all protection and replacement measures shall be consistent with applicable local jurisdiction requirements, such as the Los Angeles County Oak Tree Ordinance. Tree removal shall not be permitted until replacement trees have been planted or transplanting sites are approved. 1) For NFS and BLM lands, the USFS and BLM shall prepare a Habitat Restoration and Revegetation Plan, in discussion with LADWP, for the Project, which shall include plans for restoration, enhancement/re-vegetation and/or mitigation banking. For non-federal lands, LADWP shall prepare the Habitat Restoration and Revegetation Plan. Both plans shall include at minimum: (a) the location of the mitigation site (off-site mitigation may be required); (b) locations and details for topsoil storage; (c) the plant species to be used; (d) seed and cutting collecting guidelines; (d) a schematic depicting the mitigation area; (e) time of year that the planting will occur and the methodology of the planting; (f) a description of the irrigation methodology for container, bare-root or other planting needing irrigation; (g) measures to control exotic vegetation on site; (h) success criteria; (i) a detailed monitoring program;(j) locations and impacts to all oaks and native trees (over 3 inches DBH); (k) locations of temporary or permanent gates, barricades, or other means to control unauthorized vehicle access on access and spur roads as deemed necessary by the USFS and BLM (NFS and BLM lands only). 2) LADWP shall utilize a USFS/BLM approved locally collected seed mix, locally collected cuttings, bare-root stock, etc. to revegetate areas disturbed by construction activities. All habitats dominated by non-native species prior to Project disturbance shall be revegetated using appropriate native species.

Measure	Description
	USFS/ BLM approval is required for seeding on NFS/BLM land. The seed mix shall consist of native, locally occurring species collected from local seed sources. Cuttings and bare-root stock shall be of local origin. Restoration shall include the revegetation of stripped or exposed work sites and/or areas to be mitigated with vegetation native to the area. No commercially purchased seeds, stock, etc. will be accepted without the approval of the USFS and BLM on NFS/BLM lands, and seeds must be certified to be free of noxious weeds. Revegetation shall include ground cover, grass, shrub, and tree species in order to match disturbed areas to surrounding conditions and to restore or improve wildlife habitat quality to pre-Project or higher levels. The Habitat Restoration and Revegetation Plan shall also include a monitoring element. Post seeding and planting monitoring will be yearly from years one to five and every other year from years six to ten, or until the success criteria are met. LADWP shall restore temporarily disturbed areas, including existing tower locations that are to be removed by the Project, to pre-construction conditions or the desired future conditions per the ANF LMP. If the survival and cover requirements have not been met, LADWP is responsible for replacement planting to achieve these requirements. Replacement plants shall be monitored with the same survival and growth requirements as previously mentioned. 3) On NFS land, the USFS will conduct a preconstruction evaluation of the probable impacts to all oaks and native trees in all construction-related disturbance areas. This evaluation shall be incorporated into the Habitat Restoration Plan and shall include the species and number of individuals, their DBH, location, and potential impact type. Construction within the driplines of all native trees and oak trees/shrubs, and incidental trimming or damage to trees along the proposed access/spur routes, shall not occur until the trees are evaluated by a USFS botanist or qualified arborist. This person shall identify appropriate measures to minimize tree loss, such as the placement of fence around the dripline, padding vehicles, minimizing soil removal or adding spoil around driplines, and the placement of matting under the existing dripline during construction activities. On the ANF, if a tree must have any construction-related activities such as equipment or soil staging within the drip zone, root pruning, or excessive branch pruning (greater than 25% in one year), then the tree must be monitored for five years for tree mortality. If any of these identified trees dies during the monitoring period, then the tree must be replaced at the rate appropriate to the DBH. 4) The replacement ratios (using rooted plants in liners or direct planting of acorns [for oaks]) for native trees or any oaks that are to be removed on the ANF shall be as follows: trees from 1 to 5 inches DBH shall be replaced at 3:1; trees from 5 to 12 inches shall be replaced at 5:1; trees from 12 to 24 inches shall be replaced at 10:1; trees from 24 to 36 inches shall be replaced at 15:1; and all oaks greater than 36 inches shall be replanted at a ratio of 20:1. The replacement ratio for damaged trees shall be 2:1 for trees with DBH less than 12 inches and a 5:1 ratio for trees with DBH greater than 12 inches. The DBHs for scrub oaks will be measured following California Department of Fish and Game (CDFG) guidelines. On the ANF. any oak or native tree that must be removed or killed as a result of construction or other Project-related activities shall be replaced in kind or mitigated (off-site) at a comparable value. Compliance shall be evaluated annually for years one to five and bi-annually for years six to ten (years after tree planting). Trees shall be planted at locations acceptable to the landowner or managing agency. All planting locations, procedures, and results shall be evaluated by a qualified arborist and USFS botanist. On non-federal lands, all protection and replacement measures shall be consistent with applicable local jurisdiction requirements, such as the Los Angeles County Oak Tree Ordinance. 5) Permanent impacts on federal lands shall be determined by the appropriate federal manager (USFS and BLM) at the ratios stated in Table BIO-MM-1 (see the Biological Resources Technical Report) or at a comparable value. On NFS and BLM lands, impacts will be considered permanent if the trees are not likely to recover by ten years post-disturbance. Where on-site restoration is planned for mitigation of temporary impacts to vegetation communities, LADWP shall identify a Habitat Restoration Specialist, where concurrence has been provided by the USFS, to implement the method of restoration outlined by the USFS/BLM in the Habitat Restoration Plan. 6) On USFS/BLM lands, the creation or restoration of habitat shall be monitored after mitigation site construction to assess progress and identify potential problems with the restoration site. This will be monitored on USFS/BLM lands until the success criteria are met, or annually for years one to five, and bi-annually for years six to ten. Remediation activities (e.g., additional planting, removal of non-native invasive species, or erosion control) shall be taken during the ten-year period if necessary to ensure the success of the restoration effort. If the mitigation fails to meet the established performance criteria after the ten-year maintenance and monitoring period, monitoring and remedial activities shall

Measure	Description
	extend beyond the ten-year period until the criteria are met or unless otherwise specified by the USFS/BLM (as appropriate). If a fire occurs in a revegetation area within the ten-year monitoring period, LADWP shall be responsible for a one-time replacement. If a second fire occurs, no replanting is required, unless the fire is caused by LADWP activity. Off-site mitigation for NFS/BLM and non-NFS/BLM lands may be required if mitigation rates exceed what can be achieved on NFS/BLM land. This may be in the form of funding for land purchase for inclusion into the Angeles National Forest, mitigation banking, removing existing structures, or comparable restoration efforts. **1b.** During and after construction, USFS/BLM-identified entrances to access roads on NFS/BLM lands shall be gated or blockaded in some manner and maintained to prevent the unauthorized use of these roads by the general public. Signs prohibiting unauthorized use of the access roads shall be posted on these gates. **1c. Treat cut tree stumps with Sporax.** All stumps of trees (conifers and hardwoods) resulting from activities associated with construction of the Project shall be treated with Sporax according to product directions to prevent the spread of annosus root disease. Only licensed applicators shall apply Sporax. Sporax shall not be used during rain events unless otherwise approved by the USFS.
BIO – 2	*The following prescriptions would prevent the spread of invasive weeds into previously uninfested areas in the designated construction right-of-way.* **2a Prepare and implement a Weed Control Plan.** LADWP/ANF/BLM shall prepare and implement a comprehensive, adaptive Weed Control Plan on NFS/BLM lands for pre-construction and construction invasive weed abatement. The long-term Weed Control Plan, including monitoring and eradication, will be defined as part of the 50 year Operations and Maintenance Permit. On the ROW easement lands administered by the USFS/BLM, the Weed Control Plan shall incorporate all appropriate and legal agency-stipulated regulations. The Weed Control Plan shall be submitted to the USFS/BLM for final authorization of weed control methods, practices, and timing prior to implementation of the Weed Control Plan on public lands. Weed control on BLM lands using pesticides will require an approved BLM Pesticide Use Permit. Pesticide Use Permits are issued for a maximum of three years. ROW easements located on private lands shall include adaptive provisions such as wheel and equipment washing for the implementation of the Weed Control Plan. The Weed Control Plan shall include the following: 1) A pre-construction weed inventory shall be conducted on NFS and BLM lands by surveying all areas subject to ground-disturbing activity, including, but not limited to, tower pad preparation and construction areas, tower removal sites, pulling and tensioning sites, assembly yards, and areas subject to grading for new or improved access and spur roads. Weed populations that: (1) are rated High or Moderate for negative ecological impact in the California Invasive Plant Inventory Database (Cal-IPC 2006); (2) aid and promote the spread of wildfires (such as cheatgrass, Saharan mustard, and medusa head); and (3) are considered by the USFS and/or BLM as species of priority (for NFS/BLM lands only) shall be mapped and described according to density and area covered. In areas subject to ground disturbance, weed infestations shall be treated prior to construction according to control methods and practices for invasive weed populations designed in consultation with the USFS/BLM. The Weed Control Plan shall be updated and utilized for eradication and monitoring post-construction. 2) Weed control treatments shall include all legally permitted herbicide, manual, and mechanical methods applied with the authorization of the USFS/BLM. The application of herbicides shall be in compliance with all State and federal laws and regulations under the prescription of a Pest Control Advisor (PCA), where concurrence has been provided by the USFS/BLM, and implemented by a Licensed Qualified Applicator. Herbicides shall not be applied during or within 72 hours of a scheduled rain event. Herbicides shall not be used within Riparian Conservation Areas (RCAs) on the ANF without approval of the USFS. In riparian areas, only water-safe herbicides shall be used. Herbicides shall not be applied when wind velocities exceed 6 mph. Where manual and/or mechanical methods are used, disposal of the plant debris will follow the regulations set by the USFS/BLM. The timing of the weed control treatment shall be determined for each plant species in consultation with the USFS/BLM (on NFS/BLM lands) with the goal of controlling populations before they start producing seeds. For the preconstruction and construction of the Project, measures to control the introduction and spread of noxious weeds in the Project work area shall be taken as follows. 3) On the ANF and BLM lands, surveying for new invasive weed populations and the monitoring of identified and treated populations shall be required at all sites impacted by construction (tower pads, staging areas, landing zones, etc.), including access/spur roads disturbed during the Project.

Measure	Description
	Surveying and monitoring for weed infestations shall occur annually for years one to five and bi-annually for years six to ten, or until success criteria are met. Treatment of all identified weed populations shall occur at an appropriate interval so as to meet the success criteria. When no new seedlings or resprouts are observed at treated sites for three consecutive, normal rainfall years, the weed population can be considered eradicated and weed control efforts may cease for that impact site. 4) During Project preconstruction and construction, all seeds and straw materials shall be weed-free rice straw, and all gravel and fill material shall be certified weed-free by the county Agriculture Commissioners' Offices. Any deviation from this must be approved by a USFS/BLM botanist. All plant materials used during restoration shall be native, certified weed-free, and approved by the USFS/BLM. 5) Prior to beginning preconstruction activities, the USFS, in coordination with LADWP, will determine suitable locations to install field washing stations as part of the Weed Control Plan. Prior to commencing construction activities, LADWP shall document that all vehicles, equipment, and tools used on the Project have been cleaned at existing construction yards or legally operating car washes. This is a one-time requirement designed to address the potential of new species of weeds being transported from outside the area. If, however, vehicles, equipment, or tools are used or driven off paved roads on non-NFS lands, washing must occur prior to entering USFS lands. During Project preconstruction and construction, all vehicles, equipment, or tools which will be used outside of permitted Project roadways shall be washed at the nearest station before operating off-road. In other areas also designated by the USFS, vehicles, equipment, and tools will be washed at the nearest station after exiting those areas. Vehicles that do not leave permitted Project roadways are not required to be washed after the initial washing described above. All washing shall take place where rinse water is collected and disposed of in either a sanitary sewer or landfill, unless otherwise approved by the USFS. Written daily logs shall be kept for all vehicle/equipment/tool washing that states the date, time, location, type of equipment washed, methods used, and staff present. The log shall include the signature of a responsible staff member. Logs shall be available to the USFS for inspection at any time and shall be submitted to the USFS permit administrator on a monthly basis. 6) During Project operation and maintenance activities, weeds shall be cleared and disposed of in assembly yards, helicopter landing areas, tower pads, spur roads, staging areas, and any other disturbance areas in a USFS/BLM-approved method. **2b Remove weed seed sources from construction access routes.** Prior to construction, LADWP shall initiate invasive species eradication. Populations to be treated will be small to moderate and isolated, but have the potential to spread aggressively during construction. Post-construction, these isolated populations will be included and treated according to the restoration plan. Per the Forest Service Manual (FSM) 2080 Best Management Practice (BMP) guideline, LADWP shall also remove or reduce sources of weed seed along the travel routes associated with Project construction identified in Appendix L. To prevent the introduction or control the spread of noxious weeds, hand removal or other control methods will be implemented to reduce seed production during Project construction. Following Project approval and during the time of year when weed species can be observed and identified, LADWP shall identify, using a qualified plant ecologist, any other weed seed sources that could contribute to Project-related weed spread on the ANF and BLM lands. Target infestations identified by Project surveys should be controlled prior to construction. LADWP shall initiate eradication of the target infestations discovered during pre-construction surveys along construction routes. **2c Remove weed seed sources from assembly yards, staging areas, tower pads, pull sites, landing zones, and spur roads.** Prior to construction and during each year of use for construction at all assembly yards, staging areas, tower pads, pull sites, landing zones, and spur roads within the ANF and BLM lands, weed-infested areas should be hand-weeded and/or treated as appropriate for the individual weed species under the guidance of a qualified plant ecologist or restoration ecologist, where concurrence on the ecologist has been provided by the USFS/BLM. Unless otherwise authorized by the USFS/BLM, weed control efforts in these areas shall be timed annually to reduce shortpod mustard, tocalote, bromes and other noxious weed seed production, by hand-removing or weed-whacking infestations when flowering has just started, but before seeds have been produced. All plant debris shall be disposed of at a USFS/BLM

Measure	Description
	approved location. Weed control efforts shall commence in early spring (February – March), as indicated annually by a qualified plant ecologist or restoration ecologist in coordination with LADWP and USFS/BLM botanist or weed specialist. **2d** **Use of Herbicides to Control Exotic Weeds.** LADWP may use herbicides where deemed necessary for the control of exotic weeds within the Project area. Weed control should be species-specific, and herbicides should be applied only if necessary after considering alternate methods or as part of a proven eradication strategy for that weed species. To minimize potential impacts, weed control treatments shall include all legally permitted herbicide, manual, and mechanical methods applied with the authorization of the USFS. Due to typically large seed banks and the ability of some weed species to vigorously resprout following removal methods, most species require more than one round of treatment, or require a different follow-up treatment method after the initial removal occurs. Any herbicide use on NFS lands would be subject to the review and approval of the appropriate USFS personnel and in coordination with LADWP.
BIO – 3	*Incorporate riparian area avoidance and permit measures.* The following actions and all permit conditions detailed within the Nationwide 12 permit and RWQCB 401 water quality certification (subject to separate approval) would be implemented by the construction manager and environmental compliance monitor(s). **3a** LADWP shall not construct or modify any structure, culvert, or bridge or modify any habitat on NFS lands in RCAs without the authorization of the USFS. Vegetation removal or road construction shall not occur in RCAs during the breeding season for nesting birds (February 1 to August 15) unless otherwise approved by the USFS. LADWP shall prepare and implement a USFS RCA Treatment Plan for the Project. This Plan shall include the specific activities that will occur at each of the RCA points crossed by the Project, including the amount and type of vegetation to be cleared, the type of road crossing or improvement allowed for wet and dry crossings, and the methods that would be employed to reduce the effects of the Project on water quality. The Plan shall include seasonal restrictions for vehicle or equipment passage, restrictions on what activities may occur (such as grading, vegetation removal or tree trimming), monitoring requirements, and restoration requirements. This Plan shall be submitted to the USFS for approval prior to construction or the grading of any access road. **3b** Before construction, qualified resource specialists shall stake and flag or fence exclusion zones around all identified riparian areas. Such exclusion zones will include a 10-foot buffer to preclude sediment intrusion into the riparian areas. Earth-moving activities shall be restricted from these zones, although essential vehicle operation and foot travel will be permitted on existing roads, bridges, and crossings. All other construction activities, vehicle operation, material and equipment storage, and other surface-disturbing activities will be prohibited within the exclusion zone. **3c** In areas where riparian habitats are unavoidable, the construction manager, in consultation with the lead environmental compliance inspector and USFS, shall narrow the width of the road through the area to the minimum extent required for safe travel. New spur roads and existing access road improvements shall be constructed and implemented using methodology that preserves existing hydrology. **3d** Towers shall not be constructed in riparian areas. **3e** All temporarily disturbed riparian areas that would not be utilized for future routine operation and maintenance activities shall be restored according to the guidelines of the Habitat Restoration Plan to the extent required to ensure no net loss of habitat functions and values. Following construction activities, the areas will be restored as soon as practicable. **3f** Permanent, unavoidable losses of riparian areas will be mitigated by restoration and/or preservation of off-site habitats, as outlined in the Habitat Restoration Plan. The final mitigation and off-site restoration locations will be determined in consultation with LADWP and the responsible agency(s). Mitigation acreage ratios will be consistent with those listed in Table BIO-MM-1.
BIO – 4	*Provide restoration/compensation for affected jurisdictional areas.* **4a** Impacts to areas under jurisdiction of the USACE, RWQCB, USFS and CDFG shall be avoided to the extent feasible. Where avoidance of jurisdictional areas is not feasible, including emergency repairs, and access/spur roads within RCAs, the applicant shall provide the necessary mitigation required as part of wetland permitting. This will include creation, restoration, and/or preservation of suitable jurisdictional habitat along with adequate buffers to protect the function and values of jurisdictional area mitigation. The location(s) of the mitigation will be determined in consultation with LADWP and the responsible agency(s) as part of the wetland permitting process. **4b** Measures 3a, b, c, and d will also be incorporated to avoid and protect jurisdictional areas.

7.5.1. Types of Impacts

Below are descriptions of the criteria in which an impact would be determined significant.

Construction-related Impacts

Violation of water quality standards, creation of new sources of polluted runoff, or other degradation of water quality.
Temporary impacts to water quality could result from stormwater runoff during construction of the Project. Construction of the transmission line and the new Haskell Canyon Switching Station, and reconductoring of the existing BR-RIN line, would require ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction. Disturbed soils accelerate erosion and increase sediment in stormwater runoff to receiving waters, causing increased turbidity and sedimentation. Dewatering during construction activities could potentially release contaminated groundwater to surface water channels or drainage features. Additionally, fuel, oil, and other fluids used in construction vehicles, equipment, and heavy machinery could enter streams and contaminate water. Potential impacts to water quality from sedimentation, turbidity, and oil/chemical contamination would be less than significant. Application of GPs, and implementation of PRACTICE 2-1, 2-2, 2-3, 2-12, 7-4, 7-5, and 7-6, and mitigation measure HYD-1 would further reduce these potential impacts.

HYD-1 would minimize the potential for erosion, sedimentation, and increased turbidity by restricting where roads may be sited, minimize the use of blading for new road construction, and requiring the use of existing stream crossings, where feasible.

Substantial alteration of existing drainage patterns resulting in substantial erosion or siltation on- or off-site.
Construction of the transmission line and the new Haskell Canyon Switching Station, and reconductoring of the existing BR-RIN line would require ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction. This ground disturbance could potentially alter drainage patterns within the work areas and result in soil erosion leading to increased sedimentation. Potential impacts resulting from substantial drainage pattern alteration would be significant without mitigation. Application of GPs, and implementation of PRACTICE 2-1, 2-2, 2-4, and 7-7, and mitigation measures HYD-1, HYD-2, and HELICOPTER would reduce potential impacts resulting from substantial drainage pattern alteration to less than significant.

Substantial alteration of existing drainage patterns, including through the alteration of the course of a stream or river, or substantial increase of the rate or amount of surface runoff in a manner which would result in flooding on- or off-site.
Construction of the transmission line and the new Haskell Canyon Switching Station, and reconductoring of the existing BR-RIN line would require ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction. The proposed transmission lines would cross numerous streams and drainages, including the Santa Clara River. Ground disturbance related to construction of the proposed transmission line could potentially alter drainage patterns within the work areas and result in an increase of the rate or amount of surface water runoff. Potential impacts resulting from flooding through alteration of existing drainage patterns would be significant without mitigation. Application of GPs, and implementation of PRACTICE 2-1, 2-2, 7-4, 7-5, and 7-6, and implementation of mitigation measures HYD-1, HYD-2, and HELICOPTER would reduce potential impacts resulting from runoff or flooding through alteration of existing drainage patterns to less than significant.

HYD-2 reduces potential impacts to existing drainage patterns of streams and washes by requiring new permanent or temporary roads to be constructed in a manner that would minimize disturbance to vegetation, drainage channels, and intermittent or perennial stream banks.

HELICOPTER mitigation would, where implemented, reduce the need for access roads to be constructed on very steep slopes. This would minimize alteration of drainage patterns, as well as related erosion, siltation, and flooding.

Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems or contribution of substantial additional sources of polluted runoff.
Construction of the transmission line and the new Haskell Canyon Switching Station, and reconductoring of the existing BR-RIN line would require ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction. Creation of new permanent access and spur roads or widening of existing roads would potentially create additional sources of runoff. Likewise, grading activities for construction of the new Haskell Canyon Switching Station would potentially contribute additional sources of polluted runoff. These potential impacts would be significant without mitigation.

Potential impacts related to contribution of substantial additional sources of polluted runoff would be less than significant. Application of GPs, and implementation of PRACTICE 2-3, 2-12 and 7-4 would further reduce these potential impacts.

Have substantial adverse effect on federal protected wetlands as defined by Section 404 of the Clean Water Act through direct removal, filling, hydrological interruption, or other means.
Construction of the transmission line and the new Haskell Canyon Switching Station, and reconductoring of the existing BR-RIN line would require ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction. Construction of the new Haskell Canyon Switching Station may also require importation of soil for filling activities. These activities could impact wetlands by removing wetland vegetation and soils, or by filling wetlands with upland soils and destroying hydrological connectivity.

Potential impacts to federal protected wetlands would be less than significant. Application GPs and implementation of PRACTICE 2-1 AND 7-3 would further reduce these potential impacts.

Operation- and Maintenance-Related Impacts

Creation or contribution of runoff water which would exceed the capacity of existing or planned stormwater drainage systems, or contribution of substantial additional sources of polluted runoff.
Construction of the new Haskell Canyon Switching Station and would create new impermeable surfaces with the potential to increase the rate of stormwater runoff and contribute additional sources of polluted runoff. Maintenance of access roads and structure pads (e.g., gravelling, vegetation clearance) would also contribute additional sources of stormwater runoff. Blading and other methods of vegetation removal for clearance of roads and construction areas would decrease the ability of the soil to absorb water and increase stormwater runoff from disturbed areas. Increased runoff could result in increased erosion, and siltation and flooding downstream of the disturbed areas. Application of GPs, and implementation of PRACTICE 2-12 and 7-4, and mitigation measures HYD-3 and HYD-4 would reduce these potential impacts to less than significant.

HYD-3: New impervious areas associated with temporary construction will be restored to existing conditions, including but not limited to revegetation, to the extent possible after completion of Project construction.

HYD-4: Stormwater drainage inside switching station will be designed to minimize erosion and increase sediment control, as detailed in the SWPPP.

Placement of structures within a 100-year flood hazard area which would impede or redirect flood flows.
Construction of the new 230 kV transmission line would result in the placement of tower structures within 100-year flood hazard areas. Structures placed in these areas could potentially impede flood flows or redirect flood flows to areas not currently within a flood hazard area by raising the base flood elevation level. Implementation of PRACTICE 7-2 and mitigation measures HYD-5 and HYD-6 would reduce potential impacts resulting from impeding or redirecting flood flows to less than significant.

HYD-5: Structures and new access roads placed within a 100-year floodplain will be engineered so that they do not impede or redirect flood flows or raise the flood elevation.

HYD-7: Structures located adjacent to lakes and reservoirs will be designed to minimize damage resulting from inundation from a seismic seiche.

Other Potential Impacts

Potential Project-related impacts resulting from construction, operation, and maintenance were assessed with regards to the following significance criteria. As discussed below, the Project was determined to have no impact with regards to these criteria, which will not be discussed hereafter.

Substantial depletion of groundwater supplies or interference with groundwater recharge resulting in a net deficit of aquifer volume or lowering of level of the local groundwater table.
No Impact. Construction of steel lattice structures for the new transmission line would require concrete foundations with footings averaging a depth of 20 feet, depending on soil conditions, and construction of TSPs would require foundations from 15 feet to 30 feet deep, depending on soil conditions.

Aquifers in the BRRTP area are generally unconfined, and depths of water-bearing formations exceed the distance required for foundations and footings. While there is potential for groundwater to be encountered during auguring activities along certain segments, dewatering activities are unlikely to deplete groundwater supplies. Construction, operation, and maintenance of the Project will not interfere with groundwater recharge or otherwise lower the levels of local groundwater tables.

Placement of housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map.
No Impact. Construction of the transmission line and the new Haskell Canyon Switching Station, and reconductoring of the existing BR-RIN line does not involve the placement of housing within a 100-year flood hazard area.

Exposure of people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam.
No Impact. Although segments of the new 230 kV transmission line would be located adjacent to reservoirs, structures for the transmission line would be sited so that the line would span the area of hazard (e.g., Castaic Lake). Construction and operation of the Project would not cause or increase the likelihood of failure of a levee or dam that could result in flooding. As such, the Project would not expose people or structures to a significant risk of loss, injury, or death involving flooding resulting from the failure of a levee or dam.

8.0 IMPACT RESULTS

Project-related impacts were initially assessed without reference to USFS BMPs, GPs or MMs. Once initial impacts were determined using the methodology described in Section 7.0, BMPs, GPs and MMs were recommended and applied to each impact to minimize potential impacts resulting from construction, operation, and maintenance of BRRTP.

8.1 ALTERNATIVE 1

The Alternative 1 230 kV double-circuit transmission line would cross approximately 17 miles of ANF lands, and would affect seven 6th level watersheds: Liebre Gulch-Piru Creek, Lake Piru-Piru Creek, Fish Creek-Piru Creek, Upper Castaic Creek, Lower Bouquet Creek, Lower Castaic Creek, and San Francisquito Canyon. These watersheds have a combined area of 182,295 acres.

At the request of the USFS, a RUSLE analysis to estimate the rate of erosion resulting from construction and operation of the Project was performed for the portion of Alternative 1 that crosses the ANF. The RUSLE analysis estimated an average post-construction erosion increase of 0.68 percent (48.43 tons/acre/year), assuming no implementation of GPs, BMPs, or MMs. Of the studied watersheds, the Liebre Gulch-Piru Creek Watershed would have the largest potential increase (2.26 percent) over baseline conditions from construction of Alternative 1 (please see Appendix A for details of the RUSLE analysis).

The following subwatersheds along Alternative 1 were analyzed via WinTR-55: West Fork Liebre Gulch (ID2), Big Oak Flat (ID8), and Charlie Canyon (ID13). Results of the analysis indicated there would be no change in watershed-wide hydrograph characteristics as a result of construction of Alternative 1. In addition, these results are based on a very conservative approach: subwatersheds delineated to focus on the Alternative, assumption of 10-meter wide roads, and exclusion of any BMPs that would be mandated and monitored during construction. For a tabular and graphical representation of the model results for this subwatershed, please refer to Appendix C, Alternative 2 Results.

In the Forest, adverse effects of Alternative 1 would range from high to low before implementation of BMPs, GPs, and MMs, depending on the terrain. Alternative 1 would cross or closely parallel multiple intermittent streams, including West Fork Liebre Gulch, Trough Canyon, Posey Canyon, Big Oak Flat, Violin Canyon, Bitter Canyon, Charlie Canyon, and Dry Canyon. Alternative 1 would also cross or parallel approximately 23 RCAs. Alternative 1 would cross steep, rugged terrain (with slopes ranging from 10 percent to greater than 30 percent) where few roads exist that would be suitable for construction. Existing roads would have to be improved to allow for safe construction access and new roads would be constructed in currently roadless areas, increasing the risk of erosion and sedimentation downstream of disturbance areas; however, utilization of helicopters for construction within the steeper areas would decrease impacts resulting from erosion and sedimentation.

After implementation of GPs, PRACTICE 2-1, 2-2, 2-3, 2-12, 7-2, 7-4, 7-5, 7-6, and 7-7, and mitigation measures HYD-1, HYD-2, HYD-3, HYD-4, HYD-5, HYD-6, HYD-7, and HELICOPTER, adverse effects resulting from construction of Alternative 1 would be less than significant.

8.2 ALTERNATIVE 2

The Alternative 2 230 kV double-circuit transmission line would cross approximately 13 miles of ANF lands, and would affect three 6th level watersheds: Elizabeth Lake, San Francisquito Canyon, and Lower Bouquet Canyon. These watersheds have a combined area of 66,181 acres.

For the portion of Alternative 2 that would cross the Forest, the RUSLE analysis estimated an average post-construction erosion increase of 1.18 percent (44.43 tons/acre/year), assuming no implementation of GPs, BMPs, or MMs. Of the studied watersheds, the Elizabeth Lake Watershed would have the largest potential increase (1.59 percent) over baseline conditions from construction of Alternative 2.

Along Alternative 2, the Lake Elizabeth subwatershed (2G1) was analyzed with WinTR-55. Results of the analysis indicated there would be no change in subwatershed-wide hydrograph characteristics as a result of construction of Alternative 2. In addition, these results are based on a very conservative approach: subwatershed delineated to focus on the Alternative, assumption of 10-meter wide roads, and exclusion of any BMPs that would be mandated and monitored during construction. For a tabular and graphical representation of the model results for these subwatersheds, please refer to Appendix C, Alternative 2 Results.

In the ANF, adverse effects of Alternative 2 would range from moderate to low before implementation of BMPs, GPs, and MMs, depending on the terrain. Alternative 2 would cross or closely parallel multiple intermittent streams, including Portal Canyon, Bee Canyon, Baird Canyon, Dry Canyon, and Pettinger Canyon. Alternative 2 would also cross or parallel 16 RCAs. Alternative 2 would cross steep, rugged terrain (with slopes ranging from 10 percent to greater than 30 percent) in relatively roadless areas. Existing roads would have to be improved to allow for safe construction access and new roads would be constructed in areas where no roads currently exist, increasing potential for erosion and sedimentation in areas downstream of disturbance areas.

After implementation of GPs, PRACTICE 2-1, 2-2, 2-3, 2-12, 7-2, 7-3, 7-4, 7-5, 7-6, and 7-7, and implementation of mitigation measures HYD-1, HYD-2, HYD-3, HYD-4, HYD-5, and HYD-6, potential adverse effects resulting from construction of Alternative 2 would be less than significant.

8.3 ALTERNATIVE 2A

The Alternative 2a 230 kV double-circuit transmission line would cross approximately 16 miles of ANF lands, and would affect four 6th level watersheds: Elizabeth Lake, Elizabeth Lake Canyon, San Francisquito Canyon, and Lower Bouquet Canyon. These watersheds have a combined area of 99,685 acres.

Alternative 2a was developed after completion of the RUSLE analysis; however, given that Alternative 2a is identical to Alternative 2 with the exception of a deviation to the west around South Portal Canyon, it may be assumed the average estimated post-construction erosion increase due to construction of Alternative 2a would be similar to that of Alternative 2, keeping in mind that Alternative 2a would also cross approximately 0.7 mile of the Elizabeth Lake Canyon Watershed.

Given the overall similarity of Alternative 2a to Alternative 2, the Lake Elizabeth subwatershed (2G1) was considered as representative of watersheds affected by Alternative 2a, as well as of Alternative 2; therefore, the Lake Elizabeth subwatershed analysis results for Alternative 2 are applicable to Alternative 2a. As previously described, results of the analysis indicated there would be no change in subwatershed-wide hydrograph characteristics as a result of construction of Alternative 2a. As formerly discussed, these results are based on a very conservative approach: subwatershed delineated to focus on the Alternative, assumption of 10-meter wide roads, and exclusion of any BMPs that would be mandated and monitored during construction. For a tabular and graphical representation of the model results for this subwatershed, please refer to Appendix C, Alternative 2 Results.

In the Forest, adverse effects of Alternative 2a would range from high to low before implementation of BMPs, GPs, and MMs, depending on the terrain. Alternative 2a would cross or closely parallel multiple intermittent streams, including Bruns Canyon, South Portal Canyon, Munz Canyon, Portal Canyon, Bee Canyon, Baird Canyon, Dry Canyon, and Pettinger Canyon. Alternative 2a would also cross or parallel 16 RCAs. Alternative 2a would cross steep, rugged terrain (with slopes ranging from 10 percent to greater than 30 percent) in relatively roadless areas. Existing roads would have to be improved to allow for safe construction access and new roads would be constructed in areas where no roads currently exist, increasing potential for erosion and sedimentation in areas downstream of disturbance areas.

In the portion of Alternative 2a that would deviate to the west toward South Portal Canyon, where existing access is limited or resources are very sensitive, helicopter construction (HELICOPTER) would be utilized as a general mitigation measure to reduce the need for construction of new access roads for tower construction. This measure would minimize ground disturbance associated with crane pads, structure laydown areas, and the need for large construction vehicles and equipment. In certain areas of the Forest, new temporary access roads may be constructed for access to pulling and tensioning sites and staging areas.

After implementation of GPs, PRACTICE 2-1, 2-2, 2-3, 2-12, 7-2, 7-3, 7-4, 7-5, 7-6, and 7-7, and mitigation measures HYD-1, HYD-2, HYD-3, HYD-4, HYD-5, HYD-6, and HELICOPTER, adverse effects resulting from construction and operation of the Alternative 2a transmission line would be less than significant.

8.4 ALTERNATIVE 3

The Alternative 3 230 kV double-circuit transmission line would cross approximately 4.7 miles of ANF lands, and would affect three 6th level watersheds: Agua Dulce Canyon, Mint Canyon, and Upper Bouquet Canyon. These watersheds have a combined area of 61,995 acres.

For the portion of Alternative 3 that would cross the ANF, the RUSLE analysis estimated an average post-construction erosion increase of 1.35 percent (35.82 tons/acre/year), assuming no implementation of GPs, BMPs, or MMs. Of the studied watersheds, the Agua Dulce Canyon Watershed would have the largest potential increase (2.04 percent) over baseline conditions from construction of Alternative 3.

Along Alternative 3, the subwatershed of Unnamed Tributary of Mint Canyon (316) was analyzed using WinTR-55. Results of the analysis indicated there would be no change in subwatershed-wide hydrograph characteristics as a result of construction of Alternative 3. As with the aforementioned analyses, these results are based on a very conservative approach: subwatershed delineated to focus on the Alternative, assumption of 10-meter wide roads, and exclusion of any BMPs that would be mandated and monitored during construction. For a tabular and graphical representation of the model results for this subwatershed, please refer to Appendix C, Alternative 3 Results.

In the Forest, adverse effects of Alternative 3 would range from high to moderate before implementation of BMPs, GPs, and MMs, depending on the terrain. Alternative 3 would cross or closely parallel several intermittent streams, including Vasquez Canyon. Alternative 3 would not cross RCAs. Alternative 3 would cross steep, rugged terrain (with slopes ranging from 10 percent to greater than 30 percent). Existing roads would have to be improved to allow for safe construction access and new roads would be constructed in areas where no roads currently exist, increasing potential for erosion and sedimentation in areas downstream of disturbance areas.

After implementation of GPs, PRACTICE 2-1, 2-2, 2-3, 2-12, 7-2, 7-4, 7-5, 7-6, and 7-7, and implementation of mitigation measures HYD-1, HYD-2, HYD-3, HYD-4, HYD-5, and HYD-6, potential adverse effects resulting from construction of Alternative 3 would be less than significant.

8.5 NO ACTION ALTERNATIVE

Under the No Action Alternative, the construction of a new 230 kV transmission line, the addition of a new circuit on existing structures from Haskell Canyon to the Castaic Power Plant, the reconductoring of the existing BR-RIN transmission line, and the construction of a new Haskell Canyon Switching Station would not occur. Current, on-going operation and maintenance activities for existing facilities in the Project area would continue.

9.0 CUMULATIVE WATERSHED EFFECTS

9.1 INTRODUCTION

Cumulative effects are those effects that result from incremental impacts of the proposed action when added to other past, present and reasonably foreseeable future actions. Analysis of cumulative effects places project-specific impacts into a broader context that takes into account the full range of impacts of actions taking place over a given space and time. Cumulative effects may be considered a significant impact to the environment, as degradation of important resources may result from the combined, incremental effects of actions. Cumulative effects may result from individually minor or insignificant actions, which collectively may be considered significant as they accumulate over time and space from one or more actions or sources.

9.2 IMPACT AREA

The BRRTP Alternatives are located in 12 6th level watersheds, as described in Section 4.2, all of which are located within the greater Santa Clara River Watershed (HUC 18070102). Since the BRRTP and other projects in this region have potential to affect the entire watershed, as opposed to affecting only a smaller geographic area or subwatershed, the Santa Clara River Watershed defines the impact area for this cumulative effects analysis.

9.3 PRESENT AND REASONABLY FORESEEABLE ACTIONS

The cumulative effects analysis utilized a list of present and reasonable foreseeable projects within one-half mile radius of each Alternative. The list of projects include: 1) Electricity Transmission Projects; 2) Power Generation Projects; 3) Transportation and Public Facilities Projects; 4) Community Development Projects; 5) Recreation Projects; 6) Maintenance/Landscaping Projects; and 7) Local Development Projects. Any proposed or future project that would potentially preclude the use of, disturb, or diminish the function of a particular land use within this study area may contribute to a cumulative effect.

As the project list comprises projects in various stages of planning and development, it is likely that some of these projects would be completed as currently proposed while others would not. To be conservative, the cumulative analysis assumes that all projects listed would be built and in operation during the operating lifetime of the proposed Project.

9.3.1. Transmission Projects

Antelope Transmission Project – Construction of Southern California Edison's (SCE) proposed Antelope Transmission Project is underway and is proceeding in three sequential segments. Construction of Segments 1, 2 and 3A have been completed. Construction of Segment 3B, from Windhub Substation to and including Highwind Substation, has not started and no schedule has been developed by SCE (California Public Utilities – Current Projects).

Tehachapi Renewable Transmission Project (TRTP) – SCE is proposing to construct the TRTP, which would involve new and upgraded transmission infrastructure along 173 miles of new and existing rights-of-way, in southern Kern County, portions of Los Angeles County including the ANF, and the southwestern portion of San Bernardino County. Stated objectives for the project include providing the electrical facilities necessary to integrate levels of wind generation in excess of 700 MW and up to 4,500 MW in the Tehachapi Wind Resource Area (California Public Utilities – Current Projects).

The environmental review process for the project is currently underway. Construction began in April 2010 on approved sections. Project construction is estimated to be completed in 2015.

9.3.2. Transportation and Public Facilities

California High Speed Rail – This project proposes a ±700-mile high speed rail line from Sacramento to San Diego. The Statewide Programmatic EIS/EIR was completed in 2005, and the Bay Area to Central Valley High-Speed Train Program EIS/EIR was completed in 2008. Multiple second-tier project-level environmental documents (with preliminary engineering design) are currently underway (California High Speed Rail Authority).

Pacific Pipeline Storm Relocation Project and Access Road Repairs – Pacific Pipeline is proposing to relocate several miles of crude oil pipeline to more stable ground within the ANF. Project implementation was expected in November 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Soledad Canyon Cemex Project – The Soledad Canyon Cemex project would be a 56-million-ton sand and gravel mining project in the Soledad Canyon area. The BLM approved the project with mitigating measures in 2000, and the Interior Board of Land Appeals affirmed that decision in 2002. A City of Santa Clarita challenge to the US Supreme Court was denied in 2006. This project is pending development with ongoing challenges and delays (Cemex United States).

9.3.3. Maintenance and Landscape Management Projects

Bouquet Canyon Road Realignment – Los Angeles County Department of Public Works is proposing to straighten some sections of Bouquet Canyon Road and to raise the road surface by approximately nine feet. A Memorandum of Understanding between ANF and Los Angeles County is currently under development to initiate the project (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

San Francisquito Road Rehabilitation and Sediment Disposal Site – Los Angeles County Department of Public Works is proposing a road realignment and new bridge along San Francisquito Road within the ANF and to use eight acres of Forest land as a spoils site in support of construction activities. Public Scoping began in June 2007, and a decision was expected in September 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Old Ridge Route Storm Damage Repair – USFS is proposing to repair and provide maintenance to seven storm-damaged locations along the Old Ridge Route in ANF. A decision on the project is expected in late 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Tule Ridge/South Portal Fuels Reduction Project – USFS proposes fuels reduction and re-establishment of a fuel break to provide protection to unincorporated community of Green Valley. The project would also enhance wildlife for mammals and birds (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Jupiter Fuelbreak Project – USFS proposes to re-establish an existing fuel break that begins southwest of the unincorporated community of Green Valley and travels east, bisecting Jupiter Mountain, before heading south to Bouquet Reservoir.

Santa Clara/Mojave River Rangers District Plantation Maintenance Project – The proposed project would consist of vegetation maintenance at 13 plantations located within the ANF in order to reduce wildfire risk, and improve wildlife habitat and the vitality of individual remaining trees. Proposed actions include removal of dead trees, thinning of live trees, pruning, removing weeds, and planting for reforestation where necessary. This action was approved by the District Ranger in January 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Lake Hughes Plantation Restoration Project – The proposed project would restore unauthorized off-highway vehicle trails at the Christian and Taylor Plantations located within the ANF in order to reduce soil erosion, the spread of weeds, destruction of native plants, soil compaction, and wildlife habitat loss. Proposed actions include recontouring and decompacting soils, reseeding with native species, and reinforcing check dams. The project was approved by the District Ranger in 2009 and scheduled for implementation in January 2010 (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

Bouquet and San Francisquito Habitat Improvement Project – The project proposes invasive species removal in Bouquet and San Francisquito Canyons (Forest Service Schedule of Proposed Actions for the Angeles National Forest).

9.3.4. Local Projects

In conjunction with the major projects described above, foreseeable local projects that would potentially contribute to cumulative effects of the BRRTP watersheds were also reviewed. These proposed projects include single family residential projects, multifamily residential projects, schools, religious-related projects, public and recreational facilities, commercial and office development, hotels or motels, medical care center facilities, industrial facilities, animal facilities, and non-commercial energy facilities. These projects would be located in the following Los Angeles County Districts: Bouquet Canyon, Castaic Canyon, Leona Valley, Mount Gleason, Sand Canyon, and Soledad.

9.4 CUMULATIVE EFFECTS ANALYSIS

9.4.1. Direct and Indirect Effects Summary

Construction and operation of the BRRTP Alternatives would potentially impact water quality through ground-disturbing activities, including clearing and grading for structure installation work areas, and access construction.

Disturbed soils accelerate erosion and increase sediment in stormwater runoff to receiving waters, causing increased turbidity and sedimentation. Additionally, fuel, oil, and other fluids used in construction vehicles, equipment, and heavy machinery could enter streams and contaminate water. Project-related ground disturbance could potentially alter drainage patterns within the work areas and result in soil erosion leading to increased sedimentation or increase of the rate or amount of surface water runoff. Grading activities could also potentially create additional sources of runoff, including polluted runoff.

Dewatering during construction activities could potentially release contaminated groundwater to surface water channels or drainage features. Construction of the Project could also result in adversely impacting wetlands by removing or degrading wetland soils, damaging or removing wetland plants, or disrupting wetland hydrology. The Project would also result in placement of structures within a 100-year floodplain.

Many of the present and reasonably foreseeable projects described above involve grading activities, including large-scale grading activities that would continue for years after the BRRTP is completed. These projects would have potential to affect the impact area by altering drainage patterns, accelerating erosion, and adding additional sediment to local drainages.

Compacted or new paved areas, including railroad beds, would potentially increase the rate or amount of stormwater runoff, or create additional sources of stormwater runoff. Polluted runoff could be introduced to the impact area as oil products collect on new paved surfaces and are washed into the system with stormwater runoff. Projects using improper dewatering procedures could release contaminated groundwater into drainages within the impact area.

Along the foothills and drainages of the San Andreas Rift Zone, and within the ANF are Palustrine Emergent (PEM), Palustrine Scrub-Shrub (PSS), and Palustrine Forested (PFO) wetlands that could be filled by at least one project, and could be impacted by altered soils, vegetation, or hydrology resulting from other projects.

Most of the projects described above would cross or be located within FEMA 100-year floodplains, and would place structures within a 100-year floodplain, potentially impeding or redirecting flood flows.

9.4.2. Cumulative Effects Evaluation

Whenever multiple activities at a single site, or activities at multiple sites, produce similar or complementary changes to environmental parameters or watershed processes, the resulting impacts can be cumulatively significant, even if they are individually insignificant. For example, soil compaction resulting from construction vehicles driving over a natural surface decreases pore space and collapses conduits between pores, reducing soil porosity and permeability, and increasing runoff rates, which causes erosion. Likewise, replacement of natural surfaces with impermeable material allows a high stormwater runoff ratio and increases both peak flows and total flow volume. Removal of topsoil, which leaves mineral soil exposed, also increases the rate of stormwater flow, which in turn creates more erosion (Reid 1993). Increased and eroding stormwater flows carry increased sediment load into drainages, which increases turbidity. When these processes are occurring at multiple sites, sediment load can increase turbidity such that water temperature can increase, which in turn decreases the level of dissolved oxygen, which can lead to increased stress or death of aquatic animals.

Polluted stormwater runoff could introduce petroleum products or pathogens, or otherwise alter water chemistry, including pH levels. Runoff from multiple sources could lead to water quality impacts that exceed water quality objective thresholds. In addition, some introduced chemicals can alter the mobility or chemical composition of chemicals already present, and may contribute to nutrient deficiencies or inhibit the ability of plants to make use of available nutrients. Introduced chemicals may be deposited within streams, and repeated addition of chemicals may cause a cumulative increase in concentration (Reid 1993).

When topography is altered for construction purposes, the change in natural contours can change local and downstream hydrology. Altered hydrology can decrease water availability to wetlands, which would impact wetland plant populations and eventually create upland conditions. Altered hydrology can also modify the timing and amount of storm runoff, which could change base flows, peak flows, and flood seasonality. In response to these changes, flood frequencies could change, stream channels could be aggraded, incised, or widened, and the size distribution of streambed sediment would be modified (Reid 1993). These effects would not be limited to the physical environment, but would also affect wetland and riparian plant populations and aquatic animal populations. Changes in flood frequency and distribution could also affect human populations.

Impacts that are individually less than significant are cumulatively significant if they contribute incrementally to a cumulative impact that is already significant. For example, if a project results in sedimentation impacts that are less than significant on a project-level basis, the cumulative impact from sedimentation can be significant if the sediment is released into a stream that has not yet recovered from previous sedimentation impacts. Potential impacts to water resources resulting from construction and operation of the BRRTP may be less than significant; however, even with implementation of USFS BMPs, mitigation measures, and GPs, they would have a cumulative effect on the watersheds in which they occur as they add to the impacts of past and contemporary projects, and as the impacts of future projects are added to them. While Project-level BMPs, mitigation measures, and GPs are not sufficient to negate cumulative watershed effects, effectively implemented they are an important component of a broader watershed-scale approach to recovery from human activities.

1.0 INTRODUCTION

The City of Los Angeles Department of Water and Power (LADWP) is proposing the Barren Ridge Renewable Transmission Project (BRRTP or Project) to access clean, renewable resources in the Tehachapi Mountain and Mojave Desert areas. The Project is approximately 76 miles in length, beginning at the Barren Ridge Switching Station to Rinaldi Substation, and extends approximately 12 miles from the Castaic Power Plant to the proposed Haskell Switching Station. The proposed BRRTP includes the following:

1) Construction of approximately 61 miles of a 230 kilovolt (kV) double-circuit transmission line from the LADWP Barren Ridge Switching Station to Haskell Canyon;
2) Addition of approximately 12 miles of a 230 kV circuit on the existing double-circuit structures from Haskell Canyon to the Castaic Power Plant;
3) Upgrade of approximately 76 miles of the existing Barren Ridge-Rinaldi (BR-RIN) 230 kV transmission line with larger capacity conductors between the Barren Ridge Switching Station and the Rinaldi Substation;
4) Construction of a new electrical switching station in Haskell Canyon;
5) Expansion of the existing Barren Ridge Switching Station.

Portions of each of the three Project alternative routes would cross through the Angeles National Forest. Temporary impacts would occur where ground is disturbed for equipment staging and line work, and where construction access would be needed. Permanent impacts would result from ground disturbance required for upgrading the existing access roads and spur roads, and clearing the right-of-way.

Initial analysis of Project-related impacts revealed the potential for impacts to water quality through erosion of disturbed soils, leading to increased sedimentation and turbidity of receiving waters within the Angeles National Forest. At the request of the U.S. Forest Service (USFS), POWER Engineers, Inc. has prepared a watershed analysis to predict erosion rates (tons/acre/year) that would potentially result from construction of the alternative transmission line routes in the Angeles National Forest. This analysis allows for the comparison of potential impacts on sensitive aquatic habitat and species, and beneficial uses of waters from construction of the alternative routes within the Angeles National Forest.

2.0 METHODOLOGY

Following consultation with Mr. Paul Gregory, Hydrologist for the Angeles National Forest, the Revised Universal Soil Loss Equation, Version 2 (RUSLE) was selected to predict annual erosion from Project-related ground disturbance. The RUSLE model was run using ESRI ArcGIS 9.3.1 software. The RUSLE model predicts long-term average annual soil loss expressed in tons per acre per year (A), and is determined by the product of five factors:

$$A = R \cdot K \cdot LS \cdot C \cdot P$$

where:

A = Estimated soil loss in tons per acre per year
R = Rainfall-erosivity factor
K = Soil erodibility factor
LS = Slope length and slope steepness factor
C = Land cover management factor
P = Erosion control practice factor

The R factor represents the erosivity due to rainfall at a particular location. An average annual value of R is determined from historical weather records using erosivity values determined from individual storms, computed as the average annual sum of EI_{30}, where E is total storm kinetic energy and I_{30} is the maximum 30-minute storm intensity. The R factor accounts for both the intensity and amount of rainfall. This analysis used 4-kilometer resolution data acquired from the Natural Resource Conservation Service (NRCS) National Water and Climate Center in Portland, Oregon. This data was then converted to a 10-meter grid for calculation purposes.

The K factor represents the susceptibility of a soil to sheet and rill erosion by water. The estimates are based primarily on percentage of silt, sand, and organic matter, and on soil structure and saturated hydraulic conductivity (Ksat). For example, silt soils generally have the highest K values because silt soil particles detach easily and the sediment is easily transported. Soils with high clay content have the lowest K values because clay soils are generally plastic and resistant to detachment. K factor values from Kern, Los Angeles, and Ventura county soils were assigned based on dominant component Soil Survey Geographic (SSURGO) data from the NRCS database. Within the study area, values of K range from 0.02 to 0.32. This data was then converted to a 10-meter grid for calculation purposes.

The LS factors represent the effects of topography on erosion. The L factor represents hillslope length and the S factor represents hillslope gradient. In general, soil loss increases with increased hillslope length and gradient. To calculate the LS factor, 10-meter digital elevation model data was obtained from USGS. An automated program, RUSLE_LS_4_PC (Van Remortel *et. al*. 2007) was used to account for changes in slope from cell to cell by using a slope cut-off factor for ending/beginning slope length cumulation. For this analysis, the default cutoff values were used; a cutoff factor of 0.7 feet was used for slopes of less than five percent, and a cutoff factor of 0.5 feet was used for slopes greater than or equal to five percent.

The C factor represents the effects of land cover; specifically, the effects of vegetative cover, soil cover, soil biomass (roots and incorporated residue), and soil-disturbing activities on erosion. The C value is the average soil loss ratio weighted by the distribution of rainfall (EI) during the year. This study used a National Land Cover Dataset (NLCD) adjusted with wildfire perimeter data. The NLCD data was adjusted for both the base level RUSLE model and the proposed Project RUSLE model, to account for fires within the last 10 years. Fire data was incorporated based on the year of the burn and changing cover classes within burn areas based on the number of years since the burn occurred (see Table 1).

TABLE 1. NLCD CODES AND VEGETATION CLASSES ADJUSTED BY BURN YEAR

Burn Year	Adjusted NLCD Code and Vegetation Cover Class
2009	31 – Barren Land (Rock/Sand/Clay)
2008	31 – Barren Land (Rock/Sand/Clay)
2007	71 – Grassland/Herbaceous
2006	71 – Grassland/Herbaceous
2005	71 – Grassland/Herbaceous
2004	71 – Grassland/Herbaceous
2003	71 – Grassland/Herbaceous
2002	52 – Scrub/Shrub
2001	52 – Scrub/Shrub
2000	52 – Scrub/Shrub
1999	52 – Scrub/Shrub

Areas where fires occurred recently (2008 and 2009) were given a vegetation cover class of "barren land" since the fires had consumed all vegetation covers and soils were exposed. Over time, these areas begin to recover, with establishment of grasses and herbaceous vegetation, followed by scrub/shrub or woody vegetation providing increased soil cover and stability.

Data for areas within the Angeles National Forest indicates that annual erosion rates during the first year after a burn are 30 times greater than baseline levels. The second year after a burn, erosion rates decrease to 10 times baseline followed by seven times greater the third year, five times greater the fourth year, four times greater the fifth year, three times greater the sixth year, and two times greater the seventh year. By eight to ten years following the burn, the area has typically recovered to baseline levels (Rowe *et. al.* 1949).

For analysis of erosion resulting from the Project, C values were adjusted based on Project-related changes (*e.g.*, road construction or improvement of existing roads). The NLCD was modified for each proposed alternative where roads would require improvement. Roads requiring improvement were buffered by five meters, and underlying values (one 10-meter grid cell) were designated "barren land." Based on RUSLE2 software, RUSLE calculation procedure manuals, correlation tables, and approximate ranges from previous analyses, NLCD codes were correlated and converted to C values, as shown in Table 2. The adjusted C values were then converted to a 10-meter grid.

TABLE 2. C-FACTOR VALUES

C Factor	NLCD Code Number	Description
0	11	Open Water
0.01	21	Developed Open Space
0.01	22	Developed, Low Intensity
0.02	23	Developed, Medium Intensity
0.03	24	Developed, High Intensity
0.3	31	Barren Land
0.003	41	Deciduous Forest
0.003	42	Evergreen Forest
0.003	43	Mixed Forest
0.06	52	Scrub/Shrub
0.05	71	Grassland/Herbaceous
0.02	81	Pasture/Hay
0.09	82	Cultivated Crops
0.0003	90	Woody Wetlands
0.0006	95	Emergent Herbaceous Wetlands

The P factor represents the influence of control practices, such as contour farming, terracing, diversions, or sediment- and erosion-control best management practices (BMPs) that reduce the erosion potential of stormwater runoff. Although the P factor can be modified to account for construction disturbance and associated effectiveness of mitigation features, this variable was held constant throughout this analysis. Assignment of P values for specific disturbance and BMPs is impractical for an analysis of this scale. For an analysis of this scale, using a constant value of P is considered a conservative approach if the total area modified with increased land use factors (C factor) due to construction is overestimated. This is the case with this analysis, since C factor values were assigned in 10-meter grid increments.

Given the scale of the study area, specific data regarding implementation of erosion- and sediment-control BMPs were not included in this analysis ($P = 1$), and predicted post-construction erosion values do not reflect effects of BMP implementation. In actuality, erosion- and sediment-control BMPs and mitigation measures would be implemented throughout the Project and would reduce the potential for erosion and sedimentation.

The boundary of the watershed study area was delineated using twelve-digit/6th level hydrologic units encompassing the alternative routes within the Angeles National Forest. All data was clipped to this study area before running the RUSLE analyses.

3.0 RESULTS AND DISCUSSION

The study area encompasses 333,135 acres of highly varied terrain within the Angeles National Forest. The study area was divided according to watersheds affected by routing alternatives of the Project. The watersheds evaluated in this assessment are 6th level subwatersheds (12-digit hydrologic unit codes [HUCs]) ranging from approximately 11,409 acres to 38,533 acres and elevations of approximately 960 feet to 3,550 feet. Using the RUSLE model, baseline annual erosion rates (tons/acre/year) were estimated for each subwatershed affected by the alternative routes (Alternatives 1, 2, and 3) as shown in Figure 1. Four subwatersheds within the study area would not be affected by the BRRTP alternatives: Elizabeth Lake Canyon (180701020304), Fish Creek-Piru Creek (180701020602), Fish Canyon (180701020302), and Upper Bouquet Canyon (180701020201).

Once baseline values were estimated, the change in annual erosion rates (tons/acre/year) was estimated for each subwatershed as a result of construction of the alternative routes (*e.g.*, vegetation clearing related to road construction). Using these results, the increase of erosion from baseline conditions was calculated.

Alternative 1 would affect eight subwatersheds with a combined area of 191,957 acres. Sensitive aquatic species within these subwatersheds are arroyo toad (*Anaxyrus californicus*), California red-legged frog (*Rana draytonii*), and the Santa Ana sucker (*Catostomus santaanae*). As detailed in Table 3, estimated average baseline annual erosion level for these subwatersheds is 48.15 tons/acre/year. With construction of Alternative 1, predicted average erosion levels would be 48.43 tons/acre/year, and increase of 0.68 percent over baseline conditions. Of the eight subwatersheds, Liebre Gulch-Piru Creek would have the largest potential increase (2.26 percent) over baseline conditions from construction of Alternative 1.

Alternative 2 would affect three subwatersheds with a combined area of 65,172 acres. Sensitive aquatic species within these subwatersheds are the arroyo toad and the California red-legged frog. As detailed in Table 4, estimated average baseline annual erosion level for these subwatersheds is 43.93 tons/acre/year. With construction of Alternative 2, predicted average annual erosion would be approximately 44.43 tons/acre/year, an increase of 1.18 percent over baseline. Of the three subwatersheds, Elizabeth Lake would have the largest potential increase (1.59 percent) over baseline conditions from construction of Alternative 2.

Alternative 3 would affect three subwatersheds with a combined area of 76,006 acres. Sensitive aquatic species within these subwatersheds are the arroyo toad, California red-legged frog, and the Santa Ana sucker. Estimated average baseline annual erosion level for these subwatersheds is 35.42 tons/acre/year. As detailed in Table 5, with construction of Alternative 3, predicted average annual erosion would be 35.82 tons/acre/year, an increase of 1.35 percent over baseline. Of the three subwatersheds, Agua Dulce Canyon would have the largest potential increase (2.04 percent) over baseline conditions from construction of Alternative 3.

Rates of erosion are dependent on scale. Smaller watersheds at higher elevations tend to have higher predicted rates of erosion than larger watersheds at lower elevations. In the Angeles National Forest, smaller watersheds generally have steeper slopes and greater relief, tend to receive a greater amount of precipitation than lower-lying watersheds, and are flushed more readily by storm runoff. Vegetation also plays a role in erosion, acting as a biological barrier by intercepting precipitation and causing it to dissipate its kinetic energy on leaves and other plant structures (Howard 1982). When vegetation is removed, either by natural means (*e.g.*, wildfires) or by artificial means (*e.g.*, vegetative clearing for construction purposes), soils are left relatively open to erosive influences.

Traditionally, the RUSLE model has been applied to agricultural lands where the cover is relatively uniform and slopes are relatively level. Since its development, use of the RUSLE model has been extended to predict erosion in such non-traditional settings as construction sites, reclaimed mine spoils, and erosion on steep slopes in the tropics. In non-traditional settings where the RUSLE model generates a value for A of > 20 tons/acre/year, the expected accuracy rate is ± 35 percent (Yoder *et. al*. 2001).

The purpose of this analysis was not to calculate a precise quantity of sediment delivered to catchments within the study area, but to use the predicted volumes of soil loss to qualitatively compare the erosional effects of each BRRTP alternative route within the Angeles National Forest. In this respect, the predicted magnitude of change between pre- and post-project erosion, and between each alternative, is more useful to planners than a precise prediction of sediment delivered to a given outlet. The results of this analysis will allow for a side-by-side comparison of potential impacts from erosion resulting from each alternative, and allow for a more specific assessment of Project-related potential impacts to sensitive aquatic species within the study areas.

A RUSLE analysis was conducted for the Tehachapi Renewable Transmission Project (TRTP), also located partially within the Angeles National Forest (SCE 2009). Fourteen catchments were modeled in the TRTP analysis; catchment areas ranged from 1,879 acres to 55,471 acres (average area 19,989 acres), and predicted post-project annual erosion levels ranged between 3.6 tons/acre/year and 31.5 tons/acre/year. Predicted annual erosion increase over base values ranged from 0.4 percent to 13.0 percent (average increase over base was 4.06 percent). Predicted erosion increases predicted for the BRRTP are consistent with values predicted for the TRTP, especially considering similarities in terrain, rainfall levels, fire history, and vegetation cover between the two study areas.

It is important to note that the predicted rates of erosion do not reflect the amount of sediment that would be transported out of the watersheds; rather, the predicted values are an estimation of erosion that would occur as a result of construction and operation of the BRRTP. In actuality, much of the sediment eroded from construction areas and roads would be redeposited before leaving the watershed. A Spatially Explicit Sediment Delivery Model (SEDMOD) would be required to predict the quantity of eroded material that leaves the watersheds as sediment.

SEDMOD is expressed as follows:

$$\mathrm{SDR} = 39\ \mathrm{A}^{-1/8} + \Delta\mathrm{DP}$$

Where SDR = sediment delivery ratio
A = watershed area in square kilometers
ΔDP = difference between the composite delivery and its mean value

Delivery Potential is determined as follows:

$$\mathrm{DP} = (\mathrm{SG})\mathrm{r}(\mathrm{SG})\mathrm{w} + (\mathrm{SS})\mathrm{r}(\mathrm{SS})\mathrm{w} + (\mathrm{SP})\mathrm{r}(\mathrm{SP})\mathrm{w} + (\mathrm{ST})\mathrm{r}(\mathrm{ST})\mathrm{w} + (\mathrm{OF})\mathrm{r}(\mathrm{OF})\mathrm{w}$$

Where SG = slope gradient
SS = slope shape

SR = surface roughness
SP = stream proximity
ST = soil texture
OF = overland flow index
r = parameter rating (1 – 100)
w = weighting factor (0 – 1)

Once gross soil loss and sediment delivery ratio are determined, sediment load is estimated as follows:

$SY = A \cdot SDR$

Where SY = Sediment Yield
A = Gross Soil Loss
SDR = Sediment Delivery Ratio

SEDMOD modeling was outside the scope of this analysis; however, SEDMOD modeling using RUSLE analysis results for the TRTP watersheds estimated that only 10 percent of the predicted annual erosion would reach the catchment outlets as sediment (SCE 2009). Taking into account the similarities of topography, soils, and watershed areas between the TRTP and the BRRTP study areas, it is reasonable to expect similar predicted sediment delivery values for the BRRTP study area.

It is also important to note that, due to the scale of this analysis, the predicted post-Project erosion values do not reflect implementation of BMPs or mitigation measures. Where site conditions are modeled assuming implementation of BMPs, RUSLE erosion predictions are from 52 percent to 93 percent lower than without BMP implementation (Wachal *et. al*. 2008).

The post-Project erosion rates predicted in this analysis represent a worst-case scenario in which no BMPs or mitigation measures are implemented and all eroded material leaves the study area as sediment. The BRRTP would implement appropriate erosion- and sediment-control BMPs and mitigation measures throughout all stages of construction. Furthermore, the model reflects erosion rates within the first year after construction, and does not account for natural revegetation. Assuming the more conservative estimate of 52 percent reduction in erosion rates, implementation of erosion- and sediment-control BMPs and mitigation measures would reduce average predicted post-Project erosion rates in Alternative 1 to 48.30 tons/acre/year, in Alternative 2 to 44.18 tons/acre /year and in Alternative 3 to 35.63 tons/acre/year. Increases in erosion rates over base would average 0.33 percent in Alternative 1, in Alternative 2 to 0.58 percent, and in Alternative 3 to 0.64 percent.

APPENDIX C: ASSUMPTIONS AND RESULTS

- Calculation Assumptions
- West Fork Liebre Gulch (1D2) Model Results
- Big Oak Flat (1D8) Model Results
- Charlie Canyon (1D13) Model Results
- Lake Elizabeth (2G1) Model Results
- Unnamed Tributary of Mint Canyon (3I6) Model Results

Calculation Assumptions

General

Land Use

Conversion Table

Dirt Access Road	Impervious, Column C
Barren Land (fire)	Arid and SemiArid Rangelands, Herbaceous, Fair condition
Cultivated Crops	Cultivated Agricultural Lands, Row Crop, Straight Row, Good
Developed, Med Intensity	Residential Districts (by average lot size), 1/3 acre
Developed, OpenSp & Low Inten	Residential Districts (by average lot size), 1/2 acre
Em Herbaeous Wetlands	Impervious, Column D
Evergreen & Mixed Forest	Arid and SemiArid Rangelands, Pinyon - Juniper, Fair condition
Shrub & Scrub	Arid and SemiArid Rangelands, Sagebrush (w/grass understory), Fair condition
Water	Impervious, Column D
Woody Wetlands	Impervious, Column D

Acreage Adjustments

Four out of the five watersheds required small acreage adjustments so that the pre- and post-construction areas were equal. The differences are due to GIS processing (merging and intersecting on the outside of polygon layers. To account for these quickly, impervious area was added to Post-construction acreages in the Impervious category (Column A), or subtracted from the Scrub and Shrub area.

Time of Concentration

100 feet of Sheet flow
100 feet of Shallow concentrated
Channel velocity of 4 feet/second

Precipitation Data

Precipitation data was obtained using the following interactive website, http://dipper.nws.noaa.gov/hdsc/pfds/
A point close to the center of the watershed was chosen for the analysis.

Watershed Specific

West Fork Liebre Gulch (1D2)

0.07 Acreage adjustment, added to Post-Construction Impervious, Column A

Big Oak Flat (1D8)

0.32 Acreage adjustment, added to Post-Construction Impervious, Column A

Charlie Canyon (1D13)

Combined A & B into B for Shrub/Scrub and Pinyon/Juniper due to lack of A column
3.89 Acreage adjustment, added to Post-Construction Impervious, Column A

Lake Elizabeth (2G1)

Water and Wetlands Combined
All acreage placed in 'C' soil column to fit within winTR-55 number of cover types limitations
0.49 Acreage adjustment, subtracted from Pre-Construction Shrub/Scrub, Column A
